Chapter 1. Introduction

Overview and Features

Pegasus WMS [<http://pegasus.isi.edu>] is a configurable system for mapping and executing abstract application workflows over a wide range of execution environment including a laptop, a campus cluster, a Grid, or a commercial or academic cloud. Today, Pegasus runs workflows on Amazon EC2, Nimbus, Open Science Grid, the TeraGrid, and many campus clusters. One workflow can run on a single system or across a heterogeneous set of resources. Pegasus can run workflows ranging from just a few computational tasks up to 1 million.

Pegasus WMS bridges the scientific domain and the execution environment by automatically mapping high-level workflow descriptions onto distributed resources. It automatically locates the necessary input data and computational resources necessary for workflow execution. Pegasus enables scientists to construct workflows in abstract terms without worrying about the details of the underlying execution environment or the particulars of the low-level specifications required by the middleware (Condor, Globus, or Amazon EC2). Pegasus WMS also bridges the current cyberinfrastructure by effectively coordinating multiple distributed resources. The input to Pegasus is a description of the abstract workflow in XML format.

Pegasus allows researchers to translate complex computational tasks into workflows that link and manage ensembles of dependent tasks and related data files. Pegasus automatically chains dependent tasks together, so that a single scientist can complete complex computations that once required many different people. New users are encouraged to explore the tutorial chapter to become familiar with how to operate Pegasus for their own workflows. Users create and run a sample project to demonstrate Pegasus capabilities. Users can also browse the Useful Tips chapter to aid them in designing their workflows.

Pegasus has a number of features that contribute to its useability and effectiveness.

- **Portability / Reuse**

User created workflows can easily be run in different environments without alteration. Pegasus currently runs workflows on top of Condor, Grid infrastructures such as Open Science Grid and TeraGrid, Amazon EC2, Nimbus, and many campus clusters. The same workflow can run on a single system or across a heterogeneous set of resources.

- **Performance**

The Pegasus mapper can reorder, group, and prioritize tasks in order to increase the overall workflow performance.

- **Scalability**

Pegasus can easily scale both the size of the workflow, and the resources that the workflow is distributed over. Pegasus runs workflows ranging from just a few computational tasks up to 1 million. The number of resources involved in executing a workflow can scale as needed without any impediments to performance.

- **Provenance**

By default, all jobs in Pegasus are launched via the **kickstart** process that captures runtime provenance of the job and helps in debugging. The provenance data is collected in a database, and the data can be summaries with tools such as **pegasus-statistics**, **pegasus-plots**, or directly with SQL queries.

- **Data Management**

Pegasus handles replica selection, data transfers and output registrations in data catalogs. These tasks are added to a workflow as auxilliary jobs by the Pegasus planner.

- **Reliability**

Jobs and data transfers are automatically retried in case of failures. Debugging tools such as **pegasus-analyzer** helps the user to debug the workflow in case of non-recoverable failures.

- **Error Recovery**

When errors occur, Pegasus tries to recover when possible by retrying tasks, by retrying the entire workflow, by providing workflow-level checkpointing, by re-mapping portions of the workflow, by trying alternative data sources for staging data, and, when all else fails, by providing a rescue workflow containing a description of only the work that remains to be done. It cleans up storage as the workflow is executed so that data-intensive workflows have enough space to execute on storage-constrained resource. Pegasus keeps track of what has been done (provenance) including the locations of data used and produced, and which software was used with which parameters.

- **Operating Environments**

Pegasus workflows can be deployed across a variety of environments:

- *Local Execution*

Pegasus can run a workflow on a single computer with Internet access. Running in a local environment is quicker to deploy as the user does not need to gain access to multiple resources in order to execute a workflow.

- *Condor Pools and Glideins*

Condor is a specialized workload management system for compute-intensive jobs. Condor queues workflows, schedules, and monitors the execution of each workflow. Condor Pools and Glideins are tools for submitting and executing the Condor daemons on a Globus resource. As long as the daemons continue to run, the remote machine running them appears as part of your Condor pool. For a more complete description of Condor, see the Condor Project Pages [<http://www.cs.wisc.edu/condor/description.html>]

- *Grids*

Pegasus WMS is entirely compatible with Grid computing. Grid computing relies on the concept of distributed computations. Pegasus apportions pieces of a workflow to run on distributed resources.

- *Clouds*

Cloud computing uses a network as a means to connect a Pegasus end user to distributed resources that are based in the cloud.

Workflow Gallery

Pegasus is currently being used in a broad range of applications. To review example workflows, see the Example Workflows chapter. To see additional details about the workflows of the applications see the Gallery of Workflows [http://pegasus.isi.edu/workflow_gallery/].

We are always looking for new applications willing to leverage our workflow technologies. If you are interested please contact us at pegasus at isi dot edu.

About this Document

This document is designed to acquaint new users with the capabilities of the Pegasus Workflow Management System (WMS) and to demonstrate how WMS can efficiently provide a variety of ways to execute complex workflows on distributed resources. Readers are encouraged to take the tutorial to acquaint themselves with the components of the Pegasus System. Readers may also want to navigate through the chapters to acquaint themselves with the components on a deeper level to understand how to integrate Pegasus with your own data resources to resolve your individual computational challenges.

Chapter 2. Tutorial

Introduction

This tutorial will take you through the steps of creating and running a simple workflow using Pegasus. This tutorial is intended for new users who want to get a quick overview of Pegasus concepts and usage. The tutorial covers the creating, planning, submitting, monitoring, debugging, and generating statistics for a simple diamond-shaped workflow. More information about the topics covered in this tutorial can be found in later chapters of this user's guide.

All of the steps in this tutorial are performed on the command-line. The convention we will use for command-line input and output is to put things that you should type in bold, monospace font, and to put the output you should get in a normal weight, monospace font, like this:

```
[user@host dir]$ you type this  
you get this
```

Where `[user@host dir]$` is the terminal prompt, the text you should type is "you type this", and the output you should get is "you get this". The terminal prompt will be abbreviated as `$`. Because some of the outputs are long, we don't always include everything. Where the output is truncated we will add an ellipsis `'...'` to indicate the omitted output.

If you are having trouble with this tutorial, or anything else related to Pegasus, you can contact the Pegasus Users mailing list at <pegasus-users@isi.edu> to get help.

Getting Started

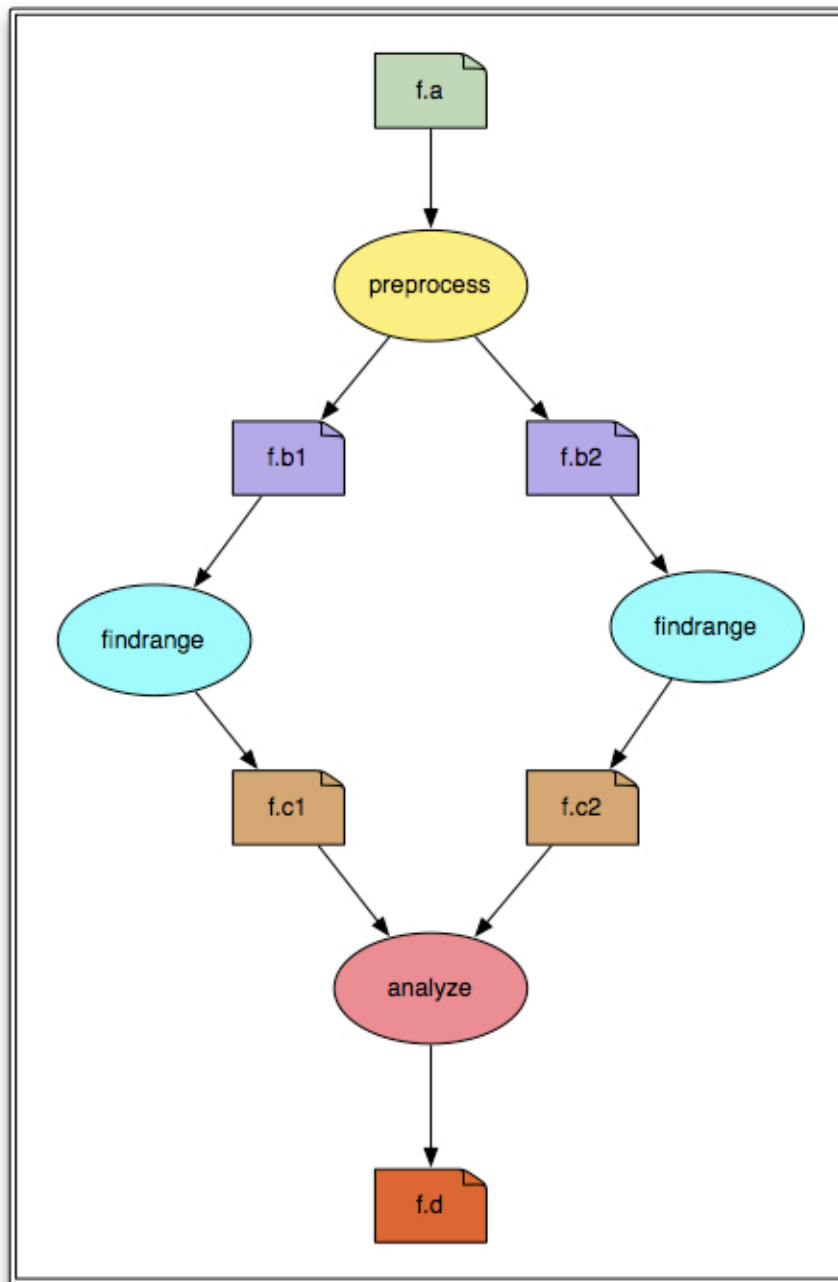

In order to reduce the amount of work required to get started we have provided several virtual machines that contain all of the software required for this tutorial. Virtual machine images are provided for VirtualBox, Amazon EC2 and FutureGrid. Information about deploying the tutorial VM on these platforms is in the appendix. Please go to the appendix for the platform you are using and follow the instructions for starting the VM found there before continuing with this tutorial.

Advanced Users: In the case that you want to install Pegasus and Condor and go through the tutorial on your own machine instead of using one of the virtual machines, the tutorial files are available in the `doc/tutorial` directory of the Pegasus source distribution. These files will need to be modified in several places to fix the paths to the users home directory (which is assumed to be `/home/tutorial`). It is assumed that Pegasus was installed from the RPM, so the path to the Pegasus install is assumed to be `/usr`. Condor should be installed in the "Personal Condor" configuration. You will also need a passwordless ssh key to enable SCP file transfers to/from localhost. Getting everything set up correctly can be tricky, so we recommend getting started with one of the VMs if you are not familiar with Condor and UNIX.

The remainder of this tutorial will assume that you have a terminal open to the directory where the tutorial files are installed. If you are using one of the tutorial VMs these files are located in the tutorial user's home directory `/home/tutorial`.

Generating the Workflow

We will be creating and running a simple diamond-shaped workflow that looks like this:

Figure 2.1. Diamond Workflow

In this diagram, the ovals represent computational jobs, the dog-eared squares are files, and the arrows are dependencies.

Pegasus reads workflow descriptions from DAX files. The term “DAX” is short for “Directed Acyclic Graph in XML”. DAX is an XML file format that has syntax for expressing jobs, arguments, files, and dependencies.

In order to create a DAX it is necessary to write code for a DAX generator. Pegasus comes with Perl, Java, and Python libraries for writing DAX generators. In this tutorial we will show how to use the Python library.

The DAX generator for the diamond workflow is in the file `generate_dax.py`. Look at the file by typing:

```
$ more generate_dax.py
```

...

Tip

We will be using the `more` command to inspect several files in this tutorial. `more` is a pager application, meaning that it splits text files into pages and displays the pages one at a time. You can view the next page of a file by pressing the spacebar. Type 'h' to get help on using `more`. When you are done, you can type 'q' to close the file.

The code has 5 sections:

1. A few system libraries and the Pegasus.DAX3 library are imported. The search path is modified to include the directory with the Pegasus Python library.
2. The name for the DAX output file is retrieved from the arguments.
3. A new ADAG object is created. This is the main object to which jobs and dependencies are added.
4. Jobs and files are added. The 4 jobs in the diagram above are added and the 6 files are referenced. Arguments are defined using strings and File objects. The input and output files are defined for each job. This is an important step, as it allows Pegasus to track the files, and stage the data if necessary. Workflow outputs are tagged with "transfer=true".
5. Dependencies are added. These are shown as arrows in the diagram above. They define the parent/child relationships between the jobs. When the workflow is executing, the order in which the jobs will be run is determined by the dependencies between them.

Generate a DAX file named `diamond.dax` by typing:

```
$ ./generate_dax.py diamond.dax
Creating ADAG...
Adding preprocess job...
Adding left Findrange job...
Adding right Findrange job...
Adding Analyze job...
Adding control flow dependencies...
Writing diamond.dax
```

The `diamond.dax` file should contain an XML representation of the diamond workflow. You can inspect it by typing:

```
$ more diamond.dax
...
```

Information Catalogs

There are three information catalogs that Pegasus uses when planning the workflow. These are the Site Catalog, Transformation Catalog, and Replica Catalog.

The Site Catalog

The site catalog describes the sites where the workflow jobs are to be executed. Typically the sites in the site catalog describe remote clusters, such as PBS clusters or Condor pools. In this tutorial we assume that you have a Personal Condor pool running on localhost. If you are using one of the tutorial VMs this has already been setup for you.

The site catalog is in `sites.xml`:

```
$ more sites.xml
...
<!-- The local site contains information about the submit host -->
<!-- The arch and os keywords are used to match binaries in the transformation catalog -->
<site handle="local" arch="x86_64" os="LINUX">
```

```

<!-- These are the paths on the submit host where Pegasus stores data -->
<!-- Scratch is where temporary files go -->
<directory type="shared-scratch" path="/home/tutorial/run">
  <file-server operation="all" url="file:///home/tutorial/run"/>
</directory>
<!-- Storage is where pegasus stores output files -->
<directory type="local-storage" path="/home/tutorial/outputs">
  <file-server operation="all" url="file:///home/tutorial/outputs"/>
</directory>

<!-- This profile tells Pegasus where to find the user's private key for SCP transfers -->
<profile namespace="env" key="SSH_PRIVATE_KEY">/home/tutorial/.ssh/id_rsa</profile>
</site>

```

...

There are two sites defined in the site catalog: “local” and “PegasusVM”. The “local” site is used by Pegasus to learn about the submit host where the workflow management system runs. The “PegasusVM” site is the personal Condor pool running on your (virtual) machine. In this case, the local site and the PegasusVM site refer to the same machine, but they are logically separate as far as Pegasus is concerned.

The local site is configured with a “storage” file system that is mounted on the submit host (indicated by the file:// URL). This file system is where the output data from the workflow will be stored. When the workflow is planned we will tell Pegasus that the output site is “local”.

The PegasusVM site is configured with a “scratch” file system accessible via SCP (indicated by the scp:// URL). This file system is where the working directory will be created. When we plan the workflow we will tell Pegasus that the execution site is “PegasusVM”.

The local site also has an environment variable called SSH_PRIVATE_KEY that tells Pegasus where to find the private key to use for SCP transfers. If you are running this tutorial on your own machine you will need to set up a passwordless ssh key and add it to authorized_keys. If you are using the tutorial VM this has already been set up for you.

Pegasus supports many different file transfer protocols. In this case the site catalog is set up so that input and output files are transferred to/from the PegasusVM site using SCP. Since both the local site and the PegasusVM site are actually the same machine, this configuration will just SCP files to/from localhost, which is just a complicated way to copy the files.

Finally, the PegasusVM site is configured with two profiles that tell Pegasus that it is a plain Condor pool. Pegasus supports many ways of submitting tasks to a remote cluster. In this configuration it will submit vanilla Condor jobs.

The Transformation Catalog

The transformation catalog describes all of the executables (called “transformations”) used by the workflow. This description includes the site(s) where they are located, the architecture and operating system they are compiled for, and any other information required to properly transfer them to the execution site and run them.

For this tutorial, the transformation catalog is in the file `tc.dat`:

```

$ more tc.dat
...
# This is the transformation catalog. It lists information about each of the
# executables that are used by the workflow.

tr preprocess {
  site PegasusVM {
    pfn "/home/tutorial/bin/preprocess"
    arch "x86_64"
    os "linux"
    type "INSTALLED"
  }
}

...

```

The `tc.dat` file contains information about three transformations: preprocess, findrange, and analyze. These three transformations are referenced in the diamond DAX. The transformation catalog indicates that all three transformations are installed on the PegasusVM site, and are compiled for x86_64 Linux.

The actual executable files are located in the `bin` directory. All three executables are actually symlinked to the same Python script. This script is just an example transformation that sleeps for 30 seconds, and then writes its own name and the contents of all its input files to all of its output files.

The Replica Catalog

The final catalog is the Replica Catalog. This catalog tells Pegasus where to find each of the input files for the workflow.

All files in a Pegasus workflow are referred to in the DAX using their Logical File Name (LFN). These LFNs are mapped to Physical File Names (PFNs) when Pegasus plans the workflow. This level of indirection enables Pegasus to map abstract DAXes to different execution sites and plan out the required file transfers automatically.

The Replica Catalog for the diamond workflow is in the `rc.dat` file:

```
$ more rc.dat
# This is the replica catalog. It lists information about each of the
# input files used by the workflow.

# The format is:
# LFN      PFN      pool="SITE"

f.a      file:///home/tutorial/input/f.a      pool="local"
```

This replica catalog contains only one entry for the diamond workflow's only input file. This entry has an LFN of "f.a" with a PFN of "file:///home/tutorial/input/f.a" and the file is stored on the local site, which implies that it will need to be transferred to the PegasusVM site when the workflow runs. The Replica Catalog uses the keyword "pool" to refer to the site. Don't be confused by this: the value of the pool variable should be the name of the site where the file is located from the Site Catalog.

Configuring Pegasus

In addition to the information catalogs, Pegasus takes a configuration file that specifies settings that control how it plans the workflow.

For the diamond workflow, the Pegasus configuration file is relatively simple. It only contains settings to help Pegasus find the information catalogs. These settings are in the `pegasus.conf` file:

```
$ more pegasus.conf
# This tells Pegasus where to find the Site Catalog
pegasus.catalog.site=XML3
pegasus.catalog.site.file=sites.xml

# This tells Pegasus where to find the Replica Catalog
pegasus.catalog.replica=File
pegasus.catalog.replica.file=rc.dat

# This tells Pegasus where to find the Transformation Catalog
pegasus.catalog.transformation=Text
pegasus.catalog.transformation.file=tc.dat
```

Planning the Workflow

The planning stage is where Pegasus maps the abstract DAX to one or more execution sites. The planning step includes:

1. Adding a job to create the remote working directory
2. Adding stage-in jobs to transfer input data to the remote working directory
3. Adding cleanup jobs to remove data from the remote working directory when it is no longer needed
4. Adding stage-out jobs to transfer data to the final output location as it is generated

5. Adding registration jobs to register the data in a replica catalog
6. Task clustering to combine several short-running jobs into a single, longer-running job. This is done to make short-running jobs more efficient.
7. Adding wrappers to the jobs to collect provenance information so that statistics and plots can be created when the workflow is finished

The `pegasus-plan` command is used to plan a workflow. This command takes quite a few arguments, so we created a `plan_dax.sh` wrapper script that has all of the arguments required for the diamond workflow:

```
$ more plan_dax.sh
...
```

The script invokes the `pegasus-plan` command with arguments for the configuration file (`--conf`), the DAX file (`-d`), the submit directory (`--dir`), the execution site (`--sites`), the output site (`-o`) and two extra arguments that prevent Pegasus from removing any jobs from the workflow (`--force`) and that prevent Pegasus from adding cleanup jobs to the workflow (`--nocleanup`).

Top plan the diamond workflow invoke the `plan_dax.sh` script with the path to the DAX file:

```
$ ./plan_dax.sh diamond.dax
2012.07.24 21:11:03.256 EDT:
```

```
I have concretized your abstract workflow. The workflow has been entered
into the workflow database with a state of "planned". The next step is to
start or execute your workflow. The invocation required is:
```

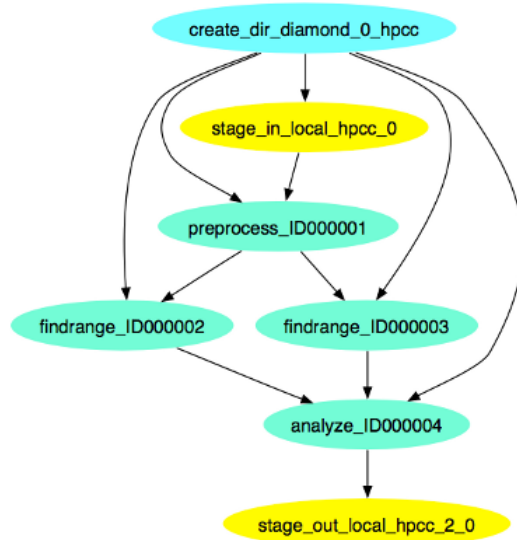

```
pegasus-run /home/tutorial/submit/tutorial/pegasus/diamond/run0001
```

```
2012.07.24 21:11:03.257 EDT: Time taken to execute is 1.103 seconds
```

Note the line in the output that starts with `pegasus-run`. That is the command that we will use to submit the workflow. The path it contains is the path to the submit directory where all of the files required to submit and monitor the workflow are stored.

This is what the diamond workflow looks like after Pegasus has finished planning the DAX:

Figure 2.2. Diamond DAG

For this workflow the only jobs Pegasus needs to add are a directory creation job, a stage-in job (for f.a), and a stage-out job (for f.d). No registration jobs are added because all the files in the DAX are marked `register="false"`, and no cleanup jobs are added because we passed the `--nocleanup` argument to `pegasus-plan`.

Submitting the Workflow

Once the workflow has been planned, the next step is to submit it to DAGMan/Condor for execution. This is done using the `pegasus-run` command. This command takes the path to the submit directory as an argument. Run the command that was printed by the `plan_dax.sh` script:

```
$ pegasus-run submit/tutorial/pegasus/diamond/run0001
-----
File for submitting this DAG to Condor      : diamond-0.dag.condor.sub
Log of DAGMan debugging messages           : diamond-0.dag.dagman.out
Log of Condor library output               : diamond-0.dag.lib.out
Log of Condor library error messages       : diamond-0.dag.lib.err
Log of the life of condor_dagman itself    : diamond-0.dag.dagman.log

Submitting job(s).
1 job(s) submitted to cluster 19.
-----

Your Workflow has been started and runs in base directory given below

cd submit/tutorial/pegasus/diamond/run0001

*** To monitor the workflow you can run ***

pegasus-status -l submit/tutorial/pegasus/diamond/run0001

*** To remove your workflow run ***
pegasus-remove submit/tutorial/pegasus/diamond/run0001
```

Monitoring the Workflow

After the workflow has been submitted you can monitor it using the `pegasus-status` command:

```
$ pegasus-status submit/tutorial/pegasus/diamond/run0001
STAT IN_STATE JOB
Run    01:48  diamond-0
Run    00:05  |-findrange_ID0000002
Run    00:05  \_findrange_ID0000003
Summary: 3 Condor jobs total (R:3)

UNREADY  READY    PRE  QUEUED    POST SUCCESS FAILURE %DONE
      2      0      0      3      0      3      0  37.5
Summary: 1 DAG total (Running:1)
```

This command shows the workflow (diamond-0) and the running jobs (in the above output it shows the two findrange jobs). It also gives statistics on the number of jobs in each state and the percentage of the jobs in the workflow that have finished successfully.

Use the `watch` command to continuously monitor the workflow:

```
$ watch pegasus-status submit/tutorial/pegasus/diamond/run0001
...
```

You should see all of the jobs in the workflow run one after the other. After a few minutes you will see:

```
(no matching jobs found in Condor Q)
UNREADY  READY    PRE  QUEUED    POST SUCCESS FAILURE %DONE
      0      0      0      0      0      8      0 100.0
Summary: 1 DAG total (Success:1)
```

That means the workflow is finished successfully. You can type `ctrl-c` to terminate the `watch` command.

If the workflow finished successfully you should see the output file `f.d` in the output directory. This file was created by the various transformations in the workflow and shows all of the executables that were invoked by the workflow:

```
$ more output/f.d
/home/tutorial/bin/analyze:
/home/tutorial/bin/findrange:
/home/tutorial/bin/preprocess:
This is the input file of the diamond workflow
```

```
/home/tutorial/bin/findrange:
/home/tutorial/bin/preprocess:
This is the input file of the diamond workflow
```

Remember that the example transformations in this workflow just print their name to all of their output files and then copy all of their input files to their output files.

Debugging the Workflow

In the case that one or more jobs fails, then the output of the `pegasus-status` command above will have a non-zero value in the `FAILURE` column.

You can debug the failure using the `pegasus-analyzer` command. This command will identify the jobs that failed and show their output. Because the workflow succeeded, `pegasus-analyzer` will only show some basic statistics about the number of successful jobs:

```
$ pegasus-analyzer submit/tutorial/pegasus/diamond/run0001
pegasus-analyzer: initializing...
```

```
*****Summary*****
```

```
Total jobs      :      7 (100.00%)
# jobs succeeded :      7 (100.00%)
# jobs failed    :      0 (0.00%)
# jobs unsubmitted :    0 (0.00%)
```

If the workflow had failed you would see something like this:

```
$ pegasus-analyzer submit/tutorial/pegasus/diamond/run0002
pegasus-analyzer: initializing...
```

```
*****Summary*****
```

```
Total jobs      :      7 (100.00%)
# jobs succeeded :      2 (28.57%)
# jobs failed    :      1 (14.29%)
# jobs unsubmitted :    4 (57.14%)
```

```
*****Failed jobs' details*****
```

```
=====preprocess_ID0000001=====
```

```
last state: POST_SCRIPT_FAILED
site: PegasusVM
submit file: preprocess_ID0000001.sub
output file: preprocess_ID0000001.out.003
error file: preprocess_ID0000001.err.003
```

```
-----Task #1 - Summary-----
```

```
site      : PegasusVM
hostname  : ip-10-252-31-58.us-west-2.compute.internal
executable : /home/tutorial/bin/preprocess
arguments  : -i f.a -o f.b1 -o f.b2
exitcode   : -128
working dir : -
```

```
-----Task #1 - preprocess - ID0000001 - stderr-----
```

```
FATAL: The main job specification is invalid or missing.
```

In this example I removed the `bin/preprocess` executable and re-planned/re-submitted the workflow (that is why the command has run0002). The output of `pegasus-analyzer` indicates that the preprocess task failed with an error message that indicates that the executable could not be found.

Collecting Statistics

The `pegasus-statistics` command can be used to gather statistics about the runtime of the workflow and its jobs. The `-s all` argument tells the program to generate all statistics it knows how to calculate:

```
$ pegasus-statistics -s all submit/tutorial/pegasus/diamond/run0001

*****SUMMARY*****
# legends
# Workflow summary:
#   Summary of the workflow execution. It shows total
#   tasks/jobs/sub workflows run, how many succeeded/failed etc.
#   In case of hierarchical workflow the calculation shows the
#   statistics across all the sub workflows. It shows the following
#   statistics about tasks, jobs and sub workflows.
#
#   * Succeeded - total count of succeeded tasks/jobs/sub workflows.
#   * Failed - total count of failed tasks/jobs/sub workflows.
#   * Incomplete - total count of tasks/jobs/sub workflows that are
#   not in succeeded or failed state. This includes all the jobs
#   that are not submitted, submitted but not completed etc. This
#   is calculated as difference between 'total' count and sum of
#   'succeeded' and 'failed' count.
#   * Total - total count of tasks/jobs/sub workflows.
#   * Retries - total retry count of tasks/jobs/sub workflows.
#   * Total Run - total count of tasks/jobs/sub workflows executed
#   during workflow run. This is the cumulative of retries,
#   succeeded and failed count.
# Workflow wall time:
#   The walltime from the start of the workflow execution to the
#   end as reported by the DAGMAN. In case of rescue dag the value
#   is the cumulative of all retries.
# Workflow cumulative job wall time:
#   The sum of the walltime of all jobs as reported by kickstart.
#   In case of job retries the value is the cumulative of all retries.
#   For workflows having sub workflow jobs (i.e SUBDAG and SUBDAX
#   jobs), the walltime value includes jobs from the sub workflows
#   as well.
# Cumulative job walltime as seen from submit side:
#   The sum of the walltime of all jobs as reported by DAGMan.
#   This is similar to the regular cumulative job walltime, but
#   includes job management overhead and delays. In case of job
#   retries the value is the cumulative of all retries. For workflows
#   having sub workflow jobs (i.e SUBDAG and SUBDAX jobs), the
#   walltime value includes jobs from the sub workflows as well.

-----
Type           Succeeded  Failed  Incomplete  Total  Retries  Total Run
Tasks           4           0         0         4      0         4
Jobs            7           0         0         7      0         7
Sub Workflows   0           0         0         0      0         0
-----

Workflow wall time:                3 mins, 25 secs, (205 s)
Workflow cumulative job wall time:  2 mins, 0 secs, (120 s)
Cumulative job walltime as seen from submit side: 2 mins, 0 secs, (120 s)

Summary: submit/tutorial/pegasus/diamond/run0001/statistics/summary.txt

*****
```

The output of `pegasus-statistics` contains many definitions to help users understand what all of the values reported mean. Among these are the total wall time of the workflow, which is the time from when the workflow was submitted until it finished, and the total cumulative job wall time, which is the sum of the runtimes of all the jobs.

The `pegasus-statistics` command also writes out several reports in the `statistics` subdirectory of the workflow submit directory:

```
$ ls submit/tutorial/pegasus/diamond/run0001/statistics/
breakdown.csv  jobs.txt      summary.txt   time.txt
breakdown.txt  summary-time.csv  time-per-host.csv  workflow.csv
jobs.csv       summary.csv    time.csv      workflow.txt
```

The file `breakdown.txt`, for example, has min, max, and mean runtimes for each transformation:

```
$ more submit/tutorial/pegasus/diamond/run0001/statistics/breakdown.txt
# legends
# Transformation - name of the transformation.
# Count          - the number of times the invocations corresponding to
#                  the transformation was executed.
```

```

# Succeeded      - the count of the succeeded invocations corresponding
#                 to the transformation.
# Failed          - the count of the failed invocations corresponding to
#                 the transformation.
# Min(sec)        - the minimum invocation runtime value corresponding to
#                 the transformation.
# Max(sec)        - the maximum invocation runtime value corresponding to
#                 the transformation.
# Mean(sec)       - the mean of the invocation runtime corresponding to
#                 the transformation.
# Total(sec)      - the cumulative of invocation runtime corresponding to
#                 the transformation.

# alf5ba03-a827-4d0a-8d59-9941cbfbd83d (diamond)
Transformation  Count  Succeeded  Failed  Min    Max    Mean    Total
analyze         1      1          0    30.008 30.008 30.008 30.008
dagman::post     7      7          0     5.0    6.0    5.143 36.0
findrange       2      2          0    30.009 30.014 30.011 60.023
pegasus::dirmanager 1      1          0     0.194 0.194 0.194 0.194
pegasus::transfer 2      2          0     0.248 0.411 0.33   0.659
preprocess      1      1          0    30.025 30.025 30.025 30.025

# All
Transformation  Count  Succeeded  Failed  Min    Max    Mean    Total
analyze         1      1          0    30.008 30.008 30.008 30.008
dagman::post     7      7          0     5.0    6.0    5.143 36.0
findrange       2      2          0    30.009 30.014 30.011 60.023
pegasus::dirmanager 1      1          0     0.194 0.194 0.194 0.194
pegasus::transfer 2      2          0     0.248 0.411 0.33   0.659
preprocess      1      1          0    30.025 30.025 30.025 30.025

```

In this case, because the example transformation sleeps for 30 seconds, the min, mean, and max runtimes for each of the analyze, findrange, and preprocess transformations are all close to 30.

Workflow Dashboard

The Virtual Box image is also bundled with the Pegasus Service bundle. This is available as a separate project in Github [<https://github.com/pegasus-isi/pegasus-service>]. The pegasus-service-server is developed in Python and uses the Flask framework to implement the web interface. The users can then connect to this server using a browser to monitor/debug workflows.

Note

The workflow dashboard can only monitor workflows which have been executed using Pegasus 4.2.0 and above.

Currently, only the Virtual Box Tutorial image for 4.3.0 has the dashboard enabled. It is not enabled in the EC2 and FutureGrid image.

By default, the server is configured to listen on all network interfaces on port 5000. A user can view the dashboard on http://<IP_ADDRESS>:5000/

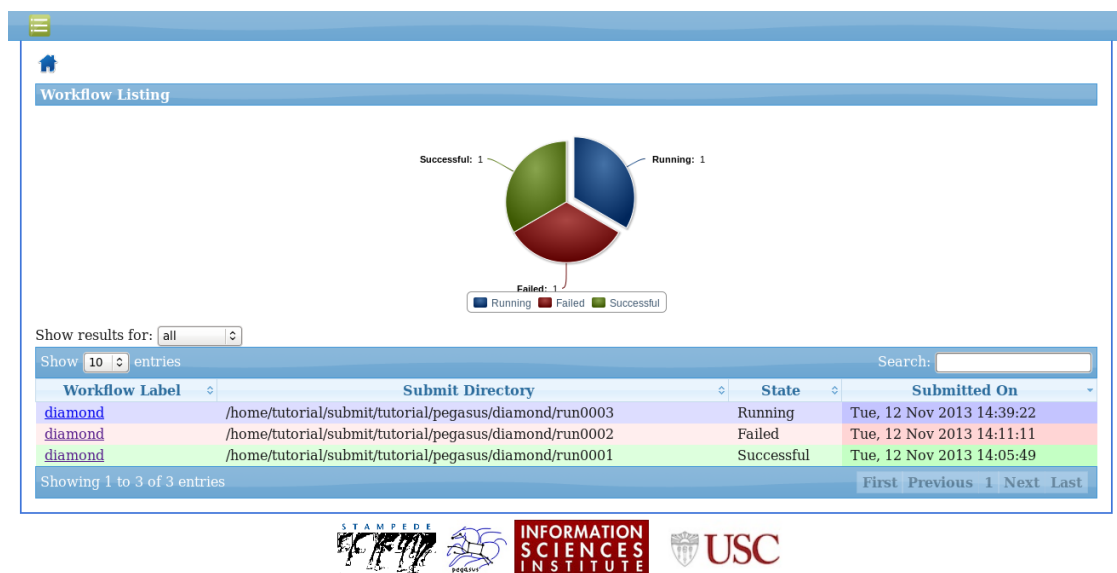

By default, the dashboard server can only monitor workflows run by the current user i.e. the user who is running the pegasus-service-server.

To access the workflow dashboard, in the Virtual BOX VM you can launch firefox by clicking the globe icon in the top menu of the desktop. The home page for the dashboard is accessible at <http://localhost:5000>

The Dashboard's home page lists all workflows, which have been run by the current-user. The home page shows the status of each of the workflow i.e. Running/Successful/Failed. The home page lists only the top level workflows (Pegasus supports hierarchical workflows i.e. workflows within a workflow). The rows in the table are color coded

- **Green:** indicates workflow finished successfully.
- **Red:** indicates workflow finished with a failure.
- **Blue:** indicates a workflow is currently running.

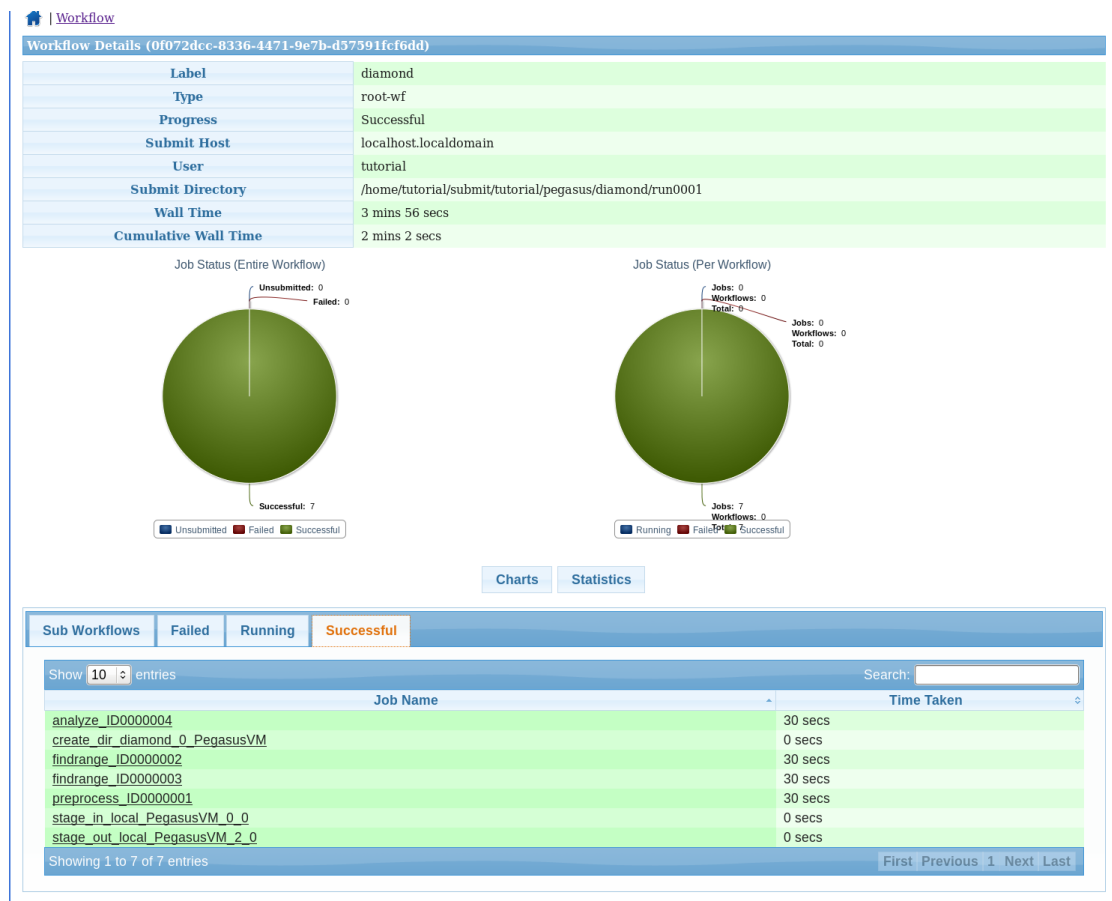

Figure 2.3. Dashboard Home Page

To view details specific to a workflow, the user can click on corresponding workflow label. The workflow details page lists workflow specific information like workflow label, workflow status, location of the submit directory, etc. The details page also displays pie charts showing the distribution of jobs based on status.

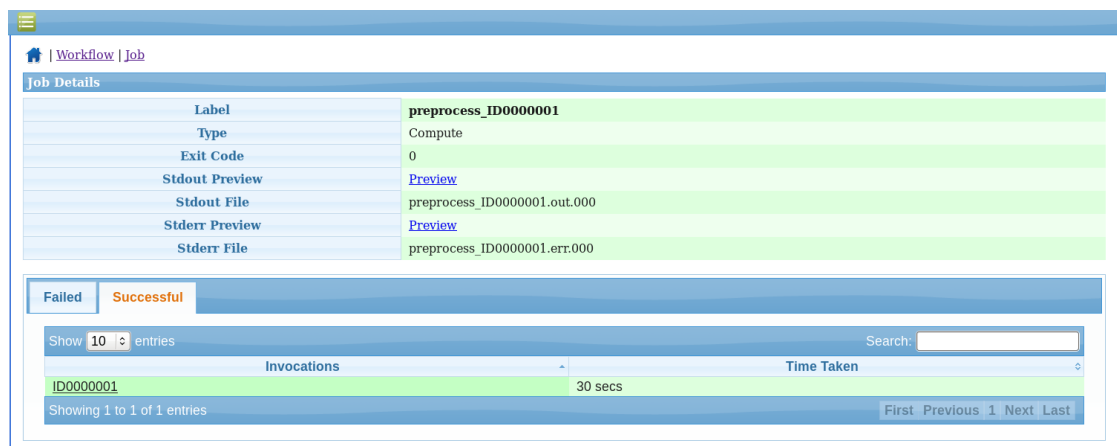

In addition, the details page displays a tab listing all sub-workflows and their statuses. Additional tabs exist which list information for all running, failed, and successful jobs.

The information displayed for a job depends on its status. For example, the failed jobs tab displays the job name, exit code, links to available standard output, and standard error contents.

Figure 2.4. Dashboard Workflow Page

To view details specific to a job the user can click on the corresponding job's job label. The job details page lists information relevant to a specific job. For example, the page lists information like job name, exit code, run time, etc.

The job details page also shows tabs for failed, and successful task invocations (Pegasus allows users to group multiple smaller task's into a single job i.e. a job may consist of one or more tasks)

Figure 2.5. Dashboard Job Description Page

The task invocation details page provides task specific information like task name, exit code, duration etc. Task details differ from job details, as they are more granular in nature.

Figure 2.6. Dashboard Invocation Page

Workflow Job Task	
Invocation Details	
Task Label	ID0000001
Transformation	preprocess
Executable	/home/tutorial/bin/transformation.py
Arguments	-i f.a -o f.b1 -o f.b2
Exit Code	0
Start Time	Tue, 12 Nov 2013 14:07:08
Remote Duration	30 secs
Remote CPU Time	0 secs

The dashboard also has web pages for workflow statistics and workflow charts, which graphically renders information provided by the pegasus-statistics and pegasus-plots command respectively.

The Statistics page shows the following statistics.

1. Workflow level statistics
2. Job breakdown statistics
3. Job specific statistics

Job Breakdown Statistics

Job Statistics

The Charts page shows the following charts.

1. Job Distribution by Count/Time
2. Time Chart by Job/Invocation
3. Workflow Execution Gantt Chart

The chart below shows the invocation distribution by count or time.

Figure 2.8. Dashboard Plots - Job Distribution

The time chart shown below shows the number of jobs/invocations in the workflow and their total runtime

Figure 2.9. Dashboard Plots - Time Chart

The workflow gantt chart lays out the execution of the jobs in the workflow over time.

Figure 2.10. Dashboard Plots - Workflow Gantt Chart

Conclusion

Congratulations! You have completed the tutorial.

If you used Amazon EC2 or FutureGrid for this tutorial make sure to terminate your VM. Refer to the appendix for more information about how to do this.

Refer to the other chapters in this guide for more information about creating, planning, and executing workflows with Pegasus.

Please contact the Pegasus Users Mailing list at <pegasus-users@isi.edu> if you need help.

Chapter 3. Installation

Prerequisites

Pegasus has a few dependencies:

- **Java 1.6 or higher.** Check with:

```
# java -version
java version "1.6.0_07"
Java(TM) 2 Runtime Environment, Standard Edition (build 1.6.0_07-164)
Java HotSpot(TM) Client VM (build 1.6.0_07-87, mixed mode, sharing)
```

- **Python 2.4 or higher.** Check with:

```
# python -v
Python 2.6.2
```

- **HTCondor (formerly Condor) 7.8 or higher.** See <http://www.cs.wisc.edu/htcondor/> for more information. You should be able to run `condor_q` and `condor_status`.

Optional Software

- **Globus 4.0 or higher.** Globus is only needed if you want to run against grid sites or use GridFTP for data transfers. See <http://www.globus.org/> for more information. Check Globus Installation

```
# echo $GLOBUS_LOCATION
/path/to/globus/install
```

Make sure you source the Globus environment

```
# GLOBUS_LOCATION/etc/globus-user-env.sh
```

Check the setup by running:#

```
# globus-version
5.2.0
```

Environment

To use Pegasus, you need to have the `pegasus-*` tools in your `PATH`. If you have installed Pegasus from RPM/DEB packages, the tools will be in the default `PATH`, in `/usr/bin`. If you have installed Pegasus from binary tarballs or source, add the `bin/` directory to your `PATH`.

Example for bourne shells:

```
# export PATH=/some/install/pegasus-4.3.0/bin:$PATH
```

Note

Pegasus 4.x is different from previous versions of Pegasus in that it does not require `PEGASUS_HOME` to be set or sourcing of any environment setup scripts.

If you want to use the DAX APIs, you might also need to set your `PYTHONPATH`, `PERL5LIB`, or `CLASSPATH`. The right setting can be found by using `pegasus-config`:

```
# export PYTHONPATH=`pegasus-config --python`
# export PERL5LIB=`pegasus-config --perl`
# export CLASSPATH=`pegasus-config --classpath`
```

Native Packages (RPM/DEB)

The preferred way to install Pegasus is with native (RPM/DEB) packages. It is recommended that you also install HTCondor (formerly Condor) (yum [<http://research.cs.wisc.edu/htcondor/yum/>], debian [<http://research.cs.wisc.edu/htcondor/debian/>]) from native packages.

RHEL / CentOS / Scientific Linux

Add the Pegasus repository to yum downloading the Pegasus repos file and adding it to `/etc/yum.repos.d/`. For RHEL 5 based systems:

```
# wget -O /etc/yum.repos.d/pegasus.repo http://download.pegasus.isi.edu/wms/download/rhel/5/
pegasus.repo
```

For RHEL 6 based systems:

```
# wget -O /etc/yum.repos.d/pegasus.repo http://download.pegasus.isi.edu/wms/download/rhel/6/
pegasus.repo
```

Search for, and install Pegasus:

```
# yum search pegasus
pegasus.x86_64 : Workflow management system for Condor, grids, and clouds
# yum install pegasus
Running Transaction
Installing      : pegasus

Installed:
pegasus      :4.3.0-1
```

Complete!

Debian

To be able to install and upgrade from the Pegasus apt repository, you will have to trust the repository key. You only need to add the repository key once:

```
# gpg --keyserver pgp.mit.edu --recv-keys 81C2A4AC
# gpg -a --export 81C2A4AC | apt-key add -
```

Add the Pegasus apt repository to your `/etc/apt/sources.list` file:

```
deb http://download.pegasus.isi.edu/wms/download/debian wheezy main
```

Install Pegasus with **apt-get** :

```
# apt-get update
...
# apt-get install pegasus
```

Pegasus from Tarballs

The Pegasus prebuild tarballs can be downloaded from the *Pegasus Download Page* [<http://pegasus.isi.edu/downloads>].

Use these tarballs if you already have HTCondor installed or prefer to keep the HTCondor installation separate from the Pegasus installation.

- Untar the tarball

```
# tar xzf pegasus-*.tar.gz
```

- include the Pegasus bin directory in your PATH

```
# export PATH=/path/to/pegasus-4.3.0:$PATH
```

Chapter 4. Creating Workflows

Abstract Workflows (DAX)

The DAX is a description of an abstract workflow in XML format that is used as the primary input into Pegasus. The DAX schema is described in `dax-3.4.xsd` [<http://pegasus.isi.edu/wms/docs/schemas/dax-3.4/dax-3.4.xsd>] The documentation of the schema and its elements can be found in `dax-3.4.html` [<http://pegasus.isi.edu/wms/docs/schemas/dax-3.4/dax-3.4.html>].

A DAX can be created by all users with the DAX generating API in Java, Perl, or Python format

Note

We highly recommend using the DAX API.

Advanced users who can read XML schema definitions can generate a DAX directly from a script

The sample workflow below incorporates some of the elementary graph structures used in all abstract workflows.

- **fan-out**, **scatter**, and **diverge** all describe the fact that multiple siblings are dependent on fewer parents.

The example shows how the **Job 2 and 3** nodes depend on **Job 1** node.

- **fan-in**, **gather**, **join**, and **converge** describe how multiple siblings are merged into fewer dependent child nodes.

The example shows how the **Job 4** node depends on both **Job 2 and Job 3** nodes.

- **serial execution** implies that nodes are dependent on one another, like pearls on a string.
- **parallel execution** implies that nodes can be executed in parallel

Figure 4.1. Sample Workflow

The example diamond workflow consists of four nodes representing jobs, and are linked by six files.

- Required input files must be registered with the Replica catalog in order for Pegasus to find it and integrate it into the workflow.
- Leaf files are a product or output of a workflow. Output files can be collected at a location.
- The remaining files all have lines leading to them and originating from them. These files are products of some job steps (lines leading to them), and consumed by other job steps (lines leading out of them). Often, these files represent intermediary results that can be cleaned.

There are two main ways of generating DAX's

1. Using a DAX generating API in Java, Perl or Python.

Note: We recommend this option.

2. Generating XML directly from your script.

Note: This option should only be considered by advanced users who can also read XML schema definitions.

One example for a DAX representing the example workflow can look like the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- generated: 2010-11-22T22:55:08Z -->
<adag xmlns="http://pegasus.isi.edu/schema/DAX"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://pegasus.isi.edu/schema/DAX http://pegasus.isi.edu/schema/
dax-3.2.xsd"
      version="3.2" name="diamond" index="0" count="1">
  <!-- part 2: definition of all jobs (at least one) -->
  <job namespace="diamond" name="preprocess" version="2.0" id="ID000001">
    <argument>-a preprocess -T60 -i <file name="f.a" /> -o <file name="f.b1" /> <file name="f.b2" /
  </argument>
    <uses name="f.b2" link="output" register="false" transfer="false" />
    <uses name="f.b1" link="output" register="false" transfer="false" />
    <uses name="f.a" link="input" />
  </job>
  <job namespace="diamond" name="findrange" version="2.0" id="ID000002">
    <argument>-a findrange -T60 -i <file name="f.b1" /> -o <file name="f.c1" /></argument>
    <uses name="f.b1" link="input" register="false" transfer="false" />
    <uses name="f.c1" link="output" register="false" transfer="false" />
  </job>
  <job namespace="diamond" name="findrange" version="2.0" id="ID000003">
    <argument>-a findrange -T60 -i <file name="f.b2" /> -o <file name="f.c2" /></argument>
    <uses name="f.c2" link="output" register="false" transfer="false" />
    <uses name="f.b2" link="input" register="false" transfer="false" />
  </job>
  <job namespace="diamond" name="analyze" version="2.0" id="ID000004">
    <argument>-a analyze -T60 -i <file name="f.c1" /> <file name="f.c2" /> -o <file name="f.d" /></
argument>
    <uses name="f.c2" link="input" register="false" transfer="false" />
    <uses name="f.d" link="output" register="false" transfer="true" />
    <uses name="f.c1" link="input" register="false" transfer="false" />
  </job>
  <!-- part 3: list of control-flow dependencies -->
  <child ref="ID000002">
    <parent ref="ID000001" />
  </child>
  <child ref="ID000003">
    <parent ref="ID000001" />
  </child>
  <child ref="ID000004">
    <parent ref="ID000002" />
    <parent ref="ID000003" />
  </child>
</adag>
```

The example workflow representation in form of a DAX requires external catalogs, such as transformation catalog (TC) to resolve the logical job names (such as diamond::preprocess:2.0), and a replica catalog (RC) to resolve the input file `f.a`. The above workflow defines the four jobs just like the example picture, and the files that flow between the jobs. The intermediary files are neither registered nor staged out, and can be considered transient. Only the final result file `f.d` is staged out.

Data Discovery (Replica Catalog)

The Replica Catalog keeps mappings of logical file ids/names (LFN's) to physical file ids/names (PFN's). A single LFN can map to several PFN's. A PFN consists of a URL with protocol, host and port information and a path to a file. Along with the PFN one can also store additional key/value attributes to be associated with a PFN.

Pegasus supports the following implementations of the Replica Catalog.

1. **File**(Default)
2. **Regex**
3. **Directory**
4. **Database via JDBC**
5. **Replica Location Service**
 - **RLS**

- LRC

6. MRC

File

In this mode, Pegasus queries a file based replica catalog. The file format is a simple multicolumn format. It is neither transactionally safe, nor advised to use for production purposes in any way. Multiple concurrent instances will conflict with each other. The site attribute should be specified whenever possible. The attribute key for the site attribute is **"pool"**.

```
LFN PFN
LFN PFN a=b [...]
LFN PFN a="b" [...]
"LFN w/LWS" "PFN w/LWS" [...]
```

The LFN may or may not be quoted. If it contains linear whitespace, quotes, backslash or an equal sign, it must be quoted and escaped. The same conditions apply for the PFN. The attribute key-value pairs are separated by an equality sign without any whitespaces. The value may be quoted. The LFN sentiments about quoting apply.

The file mode is the Default mode. In order to use the File mode you have to set the following properties

1. **pegasus.catalog.replica=File**
2. **pegasus.catalog.replica.file=<path to the replica catalog file>**

Regex

In this mode, Pegasus queries a file based replica catalog. The file format is a simple multicolumn format. It is neither transactionally safe purposes in any way. Multiple concurrent instances will conflict with each other. The site attribute should be specified whenever possible. The attribute key for the site attribute is **"pool"**.

In addition users can specify regular expression based LFN's. A regular expression based entry should be qualified with an attribute named 'regex'. The attribute regex when set to true identifies the catalog entry as a regular expression based entry. Regular expressions should follow Java regular expression syntax.

For example, consider a replica catalog as shown below.

Entry 1 refers to an entry which does not use a regular expressions. This entry would only match a file named 'f.a', and nothing else.

Entry 2 refers to an entry which uses a regular expression. In this entry f.a refers to files having name as f<any-character>a i.e. faa, f.a, f0a, etc.

```
#1
f.a file:///Volumes/data/input/f.a pool="local"
#2
f.a file:///Volumes/data/input/f.a pool="local" regex="true"
```

Regular expression based entries also support substitutions. For example, consider the regular expression based entry shown below.

Entry 3 will match files with name alpha.csv, alpha.txt, alpha.xml. In addition, values matched in the expression can be used to generate a PFN.

For the entry below if the file being looked up is alpha.csv, the PFN for the file would be generated as file:///Volumes/data/input/csv/alpha.csv. Similarly if the file being lookedup was alpha.csv, the PFN for the file would be generated as file:///Volumes/data/input/xml/alpha.xml i.e. The section [0], [1] will be replaced. Section [0] refers to the entire string i.e. alpha.csv. Section [1] refers to a partial match in the input i.e. csv, or txt, or xml. Users can utilize as many sections as they wish.

```
#3
```

```
alpha\.(csv|txt|xml) file:///Volumes/data/input/[11]/[0] pool="local" regex="true"
```

Directory

In this mode, Pegasus does a directory listing on an input directory to create the LFN to PFN mappings. The directory listing is performed recursively, resulting in deep LFN mappings. For example, if an input directory \$input is specified with the following structure

```
$input
$input/f.1
$input/f.2
$input/D1
$input/D1/f.3
```

Pegasus will create the mappings the following LFN PFN mappings internally

```
f.1 file://$input/f.1 pool="local"
f.2 file://$input/f.2 pool="local"
D1/f.3 file://$input/D1/f.3 pool="local"
```

Users can optionally specify additional properties to configure the behavior of this implementation.

1. **pegasus.catalog.replica.directory.site** to specify a site attribute other than local to associate with the mappings.
2. **pegasus.catalog.replica.directory.flat.lfn** to specify whether you want deep LFN's to be constructed or not. If not specified, value defaults to false i.e. deep lfn's are constructed for the mappings.
3. **pegasus.catalog.replica.directory.url.prefix** to associate a URL prefix for the PFN's constructed. If not specified, the URL defaults to file://

Tip

pegasus-plan has **--input-dir** option that can be used to specify an input directory on the command line. This allows you to specify a separate replica catalog to catalog the locations of output files.

JDBCRC

In this mode, Pegasus queries a SQL based replica catalog that is accessed via JDBC. The sql schema's for this catalog can be found at **\$PEGASUS_HOME/sql** directory. You will have to install the schema into either PostgreSQL or MySQL by running the appropriate commands to load the two schemas **create-XX-init.sql** and **create-XX-rc.sql** where **XX** is either **my** (for MySQL) or **pg** (for PostgreSQL)

To use JDBCRC, the user additionally needs to set the following properties

1. **pegasus.catalog.replica JDBCRC**
2. **pegasus.catalog.replica.db.driver mysql**
3. **pegasus.catalog.replica.db.url=<jdbc url to the database> e.g jdbc:mysql://data-base-host.isi.edu/database-name**
4. **pegasus.catalog.replica.db.user=<database user>**
5. **pegasus.catalog.replica.db.password=<database password>**

Users can use the command line client *pegasus-rc-client* to interface to query, insert and remove entries from the JDBCRC backend.

Replica Location Service

Replica Location Service (RLS) is a distributed replica catalog, that ships with Globus. There is an index service called Replica Location Index (RLI) to which 1 or more Local Replica Catalog (LRC) report. Each LRC can contain all or a subset of mappings.

Details about RLS can be found at <http://www.globus.org/toolkit/data/rls/>

RLS

In this mode, Pegasus queries the central RLI to discover in which LRC's the mappings for a LFN reside. It then queries the individual LRC's for the PFN's. To use this mode the following properties need to be set:

1. **pegasus.catalog.replica=RLS**
2. **pegasus.catalog.replica.url=<url to the globus LRC>**

LRC

This mode is available if the user does not want to query the RLI (Replica Location Index), but instead wishes to directly query a single Local Replica Catalog. To use the LRC mode the following properties need to be set

1. **pegasus.catalog.replica=LRC**
2. **pegasus.catalog.replica.url=<url to the globus LRC>**

Details about Globus Replica Catalog and LRC can be found at <http://www.globus.org/toolkit/data/rls/>

Note

Replica Location Service is no longer officially supported by Globus.

MRC

In this mode, Pegasus queries multiple replica catalogs to discover the file locations on the grid.

To use it set

1. **pegasus.catalog.replica=MRC**

Each associated replica catalog can be configured via properties as follows.

The user associates a variable name referred to as [value] for each of the catalogs, where [value] is any legal identifier (concretely [A-Za-z][_A-Za-z0-9]*) For each associated replica catalog the user specifies the following properties

- **pegasus.catalog.replica.mrc.[value]** - specifies the type of replica catalog.
- **pegasus.catalog.replica.mrc.[value].key** - specifies a property name key for a particular catalog

For example, to query two lrcs at the same time specify the following:

- **pegasus.catalog.replica.mrc.lrc1=LRC**
- **pegasus.catalog.replica.mrc.lrc1.url=<url to the 1st globus LRC>**
- **pegasus.catalog.replica.mrc.lrc2=LRC**
- **pegasus.catalog.replica.mrc.lrc2.url=<url to the 2nd globus LRC>**

In the above example, **lrc1** and **lrc2** are any valid identifier names and **url** is the property key that needed to be specified.

Replica Catalog Client pegasus-rc-client

The client used to interact with the Replica Catalogs is pegasus-rc-client. The implementation that the client talks to is configured using Pegasus properties.

Lets assume we create a file `f.a` in your home directory as shown below.

```
$ date > $HOME/f.a
```

We now need to register this file in the **File** replica catalog located in `$HOME/rc` using the `pegasus-rc-client`. Replace the `gsiftp://url` with the appropriate parameters for your grid site.

```
$ rc-client -Dpegasus.catalog.replica=File -Dpegasus.catalog.replica.file=$HOME/rc insert \  
f.a gsiftp://somehost:port/path/to/file/f.a pool=local
```

You may first want to verify that the file registration is in the replica catalog. Since we are using a File catalog we can look at the file `$HOME/rc` to view entries.

```
$ cat $HOME/rc  
  
# file-based replica catalog: 2010-11-10T17:52:53.405-07:00  
f.a gsiftp://somehost:port/path/to/file/f.a pool=local
```

The above line shows that entry for file `f.a` was made correctly.

You can also use the `pegasus-rc-client` to look for entries.

```
$ pegasus-rc-client -Dpegasus.catalog.replica=File -Dpegasus.catalog.replica.file=$HOME/rc lookup  
LFN f.a  
  
f.a gsiftp://somehost:port/path/to/file/f.a pool=local
```

Resource Discovery (Site Catalog)

The Site Catalog describes the compute resources (which are often clusters) that we intend to run the workflow upon. A site is a homogeneous part of a cluster that has at least a single GRAM gatekeeper with a **jobmanager-fork** and `jobmanager-<scheduler>` interface and at least one **gridftp** server along with a shared file system. The GRAM gatekeeper can be either WS GRAM or Pre-WS GRAM. A site can also be a condor pool or glidein pool with a shared file system.

The Site Catalog can be described as an XML . Pegasus currently supports two schemas for the Site Catalog:

1. **XML4**(Default) Corresponds to the schema described here [<http://pegasus.isi.edu/wms/docs/schemas/sc-4.0/sc-4.0.html>].
2. **XML3**(Deprecated) Corresponds to the schema described here [<http://pegasus.isi.edu/wms/docs/schemas/sc-3.0/sc-3.0.html>]

XML4

This is the default format for Pegasus 4.2. This format allows defining filesystem of shared as well as local type on the head node of the remote cluster as well as on the backend nodes

Figure 4.2. Schema Image of the Site Catalog XML4

Below is an example of the XML4 site catalog

```
<?xml version="1.0" encoding="UTF-8"?>
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
  version="4.0">

  <site handle="local" arch="x86_64" os="LINUX">
    <directory type="shared-scratch" path="/tmp/workflows/scratch">
      <file-server operation="all" url="file:///tmp/workflows/scratch"/>
    </directory>
    <directory type="local-storage" path="/tmp/workflows/outputs">
      <file-server operation="all" url="file:///tmp/workflows/outputs"/>
    </directory>
  </site>

  <site handle="condor_pool" arch="x86_64" os="LINUX">
    <grid type="gt5" contact="smarty.isi.edu/jobmanager-pbs" scheduler="PBS"
    jobtype="auxillary"/>
    <grid type="gt5" contact="smarty.isi.edu/jobmanager-pbs" scheduler="PBS" jobtype="compute"/>
    <directory type="shared-scratch" path="/lustre">
      <file-server operation="all" url="gsiftp://smarty.isi.edu/lustre"/>
    </directory>
    <replica-catalog type="LRC" url="rlsn://smarty.isi.edu"/>
  </site>

  <site handle="staging_site" arch="x86_64" os="LINUX">
    <directory type="shared-scratch" path="/data">
      <file-server operation="put" url="scp://obelix.isi.edu/data"/>
      <file-server operation="get" url="http://obelix.isi.edu/data"/>
    </directory>
  </site>

</sitecatalog>
```

Described below are some of the entries in the site catalog.

1. **site** - A site identifier.
2. **Directory** - Info about filesystems Pegasus can use for storing temporary and long-term files. There are several configurations:
 - **shared-scratch** - This describe a scratch file systems. Pegasus will use this to store intermediate data between jobs and other temporary files.
 - **local-storage** - This describes the storage file systems (long term). This is the directory Pegasus will stage output files to.
 - **local-scratch** - This describe the scratch file systems available locally on a compute node. This parameter is not commonly used and can be left unset in most cases.

For each of the directories, you can specify access methods. Allowed methods are **put**, **get**, and **all** which means both put and get. For each mehod, specify a URL including the protocol. For example, if you want share data via http using the /var/www/staging directory, you can use scp://hostname/var/www for the put element and http://hostname/staging for the get element.

3. **arch,os,osrelease,osversion, glibc** - The arch/os/osrelease/osversion/glibc of the site. OSRELEASE, OSVERSION and GLIBC are optional

ARCH can have one of the following values X86, X86_64, SPARCV7, SPARCV9, AIX, PPC.

OS can have one of the following values LINUX,SUNOS,MACOSX. The default value for sysinfo if none specified is X86::LINUX

4. **replica-catalog** - URL for a local replica catalog (LRC) to register your files in. Only used for RLS implementation of the RC. This is optional
5. **Profiles** - One or many profiles can be attached to a pool.

One example is the environments to be set on a remote pool.

To use this site catalog the follow properties need to be set:

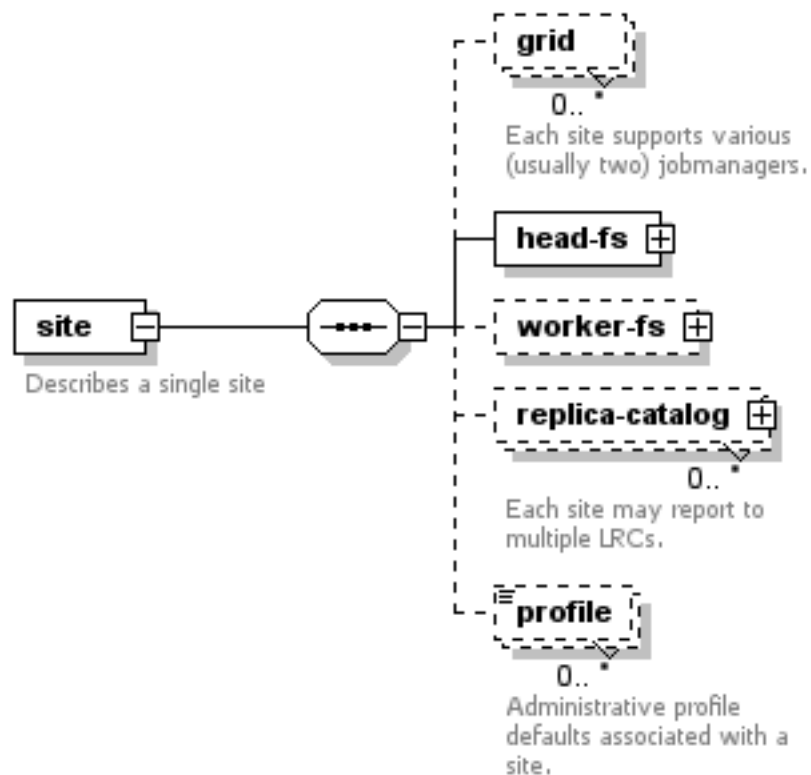

1. **pegasus.catalog.site.file**=<path to the site catalog file>

XML3

Warning

This format is now deprecated in favor of the XML4 format. If you are still using the File format you should convert it to XML4 format using the client pegasus-sc-converter

This is the default format for Pegasus 3.0. This format allows defining filesystem of shared as well as local type on the head node of the remote cluster as well as on the backend nodes

Figure 4.3. Schema Image of the Site Catalog XML 3

Below is an example of the XML3 site catalog

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog
http://pegasus.isi.edu/schema/sc-3.0.xsd" version="3.0">
  <site handle="isi" arch="x86" os="LINUX" osrelease="" osversion="" glibc="">
    <grid type="gt2" contact="smarty.isi.edu/jobmanager-pbs" scheduler="PBS" jobtype="auxillary"/>
  >
  <grid type="gt2" contact="smarty.isi.edu/jobmanager-pbs" scheduler="PBS" jobtype="compute"/>
    <head-fs>
      <scratch>
        <shared>
          <file-server protocol="gsiftp" url="gsiftp://skynet-data.isi.edu"
            mount-point="/nfs/scratch01" />
          <internal-mount-point mount-point="/nfs/scratch01"/>
        </shared>
      </scratch>
      <storage>
        <shared>
          <file-server protocol="gsiftp" url="gsiftp://skynet-data.isi.edu"
            mount-point="/exports/storage01" />
          <internal-mount-point mount-point="/exports/storage01"/>
        </shared>
      </storage>
    </head-fs>
    <replica-catalog type="LRC" url="rlsn://smarty.isi.edu"/>
    <profile namespace="env" key="PEGASUS_HOME" >/nfs/vdt/pegasus</profile>
    <profile namespace="env" key="GLOBUS_LOCATION" >/vdt/globus</profile>
  </site>
</sitecatalog>
```

Described below are some of the entries in the site catalog.

1. **site** - A site identifier.

2. **replica-catalog** - URL for a local replica catalog (LRC) to register your files in. Only used for RLS implementation of the RC. This is optional

3. **File Systems** - Info about filesystems mounted on the remote clusters head node or worker nodes. It has several configurations

- **head-fs/scratch** - This describe the scratch file systems (temporary for execution) available on the head node
- **head-fs/storage** - This describes the storage file systems (long term) available on the head node
- **worker-fs/scratch** - This describe the scratch file systems (temporary for execution) available on the worker node
- **worker-fs/storage** - This describes the storage file systems (long term) available on the worker node

Each scratch and storage entry can contain two sub entries,

- SHARED for shared file systems like NFS, LUSTRE etc.
- LOCAL for local file systems (local to the node/machine)

Each of the filesystems are defined by used a file-server element. Protocol defines the protocol uses to access the files, URL defines the url prefix to obtain the files from and mount-point is the mount point exposed by the file server.

Along with this an internal-mount-point needs to defined to access the files directly from the machine without any file servers.

4. **arch,os,osrelease,osversion, glibc** - The arch/os/osrelease/osversion/glibc of the site. OSRELEASE, OSVERSION and GLIBC are optional

ARCH can have one of the following values X86, X86_64, SPARCV7, SPARCV9, AIX, PPC.

OS can have one of the following values LINUX,SUNOS,MACOSX. The default value for sysinfo if none specified is X86::LINUX

5. **Profiles** - One or many profiles can be attached to a pool.

One example is the environments to be set on a remote pool.

To use this site catalog the follow properties need to be set:

1. **pegasus.catalog.site.file=<path to the site catalog file>**

Site Catalog Client pegasus-sc-client

The pegasus-sc-client can be used to generate a site catalog for Open Science Grid (OSG) by querying their Monitoring Interface likes VORS or OSGMM. See pegasus-sc-client --help for more details

Site Catalog Converter pegasus-sc-converter

Pegasus 4.2 by default now parses Site Catalog format conforming to the SC schema 4.0 (XML4) available here [<http://pegasus.isi.edu/wms/docs/schemas/sc-4.0/sc-4.0.xsd>] and is explained in detail in the Catalog Properties section of Running Workflows.

Pegasus 4.2 comes with a pegasus-sc-converter that will convert users old site catalog (XML3) to the XML4 format. Sample usage is given below.

```
$ pegasus-sc-converter -i sample.sites.xml -I XML3 -o sample.sites.xml4 -O XML4
```

```
2010.11.22 12:55:14.169 PST:   Written out the converted file to sample.sites.xml4
```

To use the converted site catalog, in the properties do the following:

1. unset pegasus.catalog.site or set pegasus.catalog.site to XML
2. point pegasus.catalog.site.file to the converted site catalog

Executable Discovery (Transformation Catalog)

The Transformation Catalog maps logical transformations to physical executables on the system. It also provides additional information about the transformation as to what system they are compiled for, what profiles or environment variables need to be set when the transformation is invoked etc.

Pegasus currently supports two implementations of the Transformation Catalog

1. **Text:** A multiline text based Transformation Catalog (DEFAULT)
2. **File:** A simple multi column text based Transformation Catalog
3. **Database:** A database backend (MySQL or PostgreSQL) via JDB

In this guide we will look at the format of the Multiline Text based TC.

MultiLine Text based TC (Text)

The multiline text based TC is the new default TC in Pegasus. This format allows you to define the transformations

The file is read and cached in memory. Any modifications, as adding or deleting, causes an update of the memory and hence to the file underneath. All queries are done against the memory representation. The file sample.tc.text in the etc directory contains an example

```
tr example::keg:1.0 {

#specify profiles that apply for all the sites for the transformation
#in each site entry the profile can be overridden

  profile env "APP_HOME" "/tmp/myscratch"
  profile env "JAVA_HOME" "/opt/java/1.6"

  site isi {
    profile env "HELLO" "WORLD"
    profile condor "FOO" "bar"
    profile env "JAVA_HOME" "/bin/java.1.6"
    pfn "/path/to/keg"
    arch "x86"
    os "linux"
    osrelease "fc"
    osversion "4"
    type "INSTALLED"
  }

  site wind {
    profile env "CPATH" "/usr/cpath"
    profile condor "universe" "condor"
    pfn "file:///path/to/keg"
    arch "x86"
    os "linux"
    osrelease "fc"
    osversion "4"
    type "STAGEABLE"
  }
}
```

The entries in this catalog have the following meaning

1. **tr** - A transformation identifier. (Normally a Namespace::Name:Version.. The Namespace and Version are optional.)
2. **pfn** - URL or file path for the location of the executable. The pfn is a file path if the transformation is of type INSTALLED and generally a url (file:/// or http:// or gridftp://) if of type STAGEABLE

3. **site** - The site identifier for the site where the transformation is available
4. **type** - The type of transformation. Whether it is installed ("INSTALLED") on the remote site or is available to stage ("STAGEABLE").
5. **arch, os, osrelease, osversion** - The arch/os/osrelease/osversion of the transformation. osrelease and osversion are optional.

ARCH can have one of the following values x86, x86_64, sparcv7, sparcv9, ppc, aix. The default value for arch is x86

OS can have one of the following values linux, sunos, macosx. The default value for OS if none specified is linux

6. **Profiles** - One or many profiles can be attached to a transformation for all sites or to a transformation on a particular site.

To use this format of the Transformation Catalog you need to set the following properties

1. **pegasus.catalog.transformation=Text**
2. **pegasus.catalog.transformation.file=<path to the transformation catalog file>**

Singleline Text based TC (File)

Warning

This format is now deprecated in favor of the multiline TC. If you are still using the single line TC you should convert it to multiline using the tc-converter client.

The format of the this TC is as follows.

```
#site logicaltr physicaltr type system profiles(NS::KEY="VALUE")

site1 sys::date:1.0 /usr/bin/date INSTALLED INTEL32::LINUX:FC4.2:3.6 ENV::PATH="/usr/
bin";PEGASUS_HOME="/usr/local/pegasus"
```

The system and profile entries are optional and will use default values if not specified. The entries in the file format have the following meaning:

1. **site** - A site identifier.
2. **logicaltr** - The logical transformation name. The format is NAMESPACE::NAME:VERSION where NAMESPACE and NAME are optional.
3. **physicaltr** - The physical transformation path or URL.

If the transformation type is INSTALLED then it needs to be an absolute path to the executable. If the type is STAGEABLE then the path needs to be a HTTP, FTP or gsiftp URL

4. **type** - The type of transformation. Can have one of two values
 - **INSTALLED**: This means that the transformation is installed on the remote site
 - **STAGEABLE**: This means that the transformation is available as a static binary and can be staged to a remote site.
5. **system** - The system for which the transformation is compiled.

The formation of the system is ARCH::OS:OSVERSION:GLIBC where the GLIBC and OS VERSION are optional. ARCH can have one of the following values INTEL32, INTEL64, SPARCV7, SPARCV9, AIX, AMD64. OS can have one of the following values LINUX, SUNOS. The default value for system if none specified is INTEL32::LINUX

6. **Profiles** - The profiles associated with the transformation. For indepth information about profiles and their priorities read the Profile Guide.

The format for profiles is `NS::KEY="VALUE"` where `NS` is the namespace of the profile e.g. `Pegasus,condor,DAGMan,env,globus`. The key and value can be any strings. Remember to quote the value with double quotes. If you need to specify several profiles you can do it in several ways

- `NS1::KEY1="VALUE1",KEY2="VALUE2";NS2::KEY3="VALUE3",KEY4="VALUE4"`

This is the most optimized form. Multiple key values for the same namespace are separated by a comma `,` and different namespaces are separated by a semicolon `;`

- `NS1::KEY1="VALUE1";NS1::KEY2="VALUE2";NS2::KEY3="VALUE3";NS2::KEY4="VALUE4"`

You can also just repeat the triple of `NS::KEY="VALUE"` separated by semicolons for a simple format;

To use this format of the Transformation Catalog you need to set the following properties

1. `pegasus.catalog.transformation=File`
2. `pegasus.catalog.transformation.file=<path to the transformation catalog file>`

Database TC (Database)

The database TC allows you to use a relational database. To use the database TC you need to have installed a MySQL or PostgreSQL server. The schema for the database is available in `$PEGASUS_HOME/sql` directory. You will have to install the schema into either PostgreSQL or MySQL by running the appropriate commands to load the two schemas `create-XX-init.sql` and `create-XX-tc.sql` where `XX` is either `my` (for MySQL) or `pg` (for PostgreSQL)

To use the Database TC you need to set the following properties

1. `pegasus.catalog.transformation.db.driver=MySQL | Postgres`
2. `pegasus.catalog.transformation.db.url=<jdbc url to the database>`
3. `pegasus.catalog.transformation.db.user=<database user>`
4. `pegasus.catalog.transformation.db.password=<database password>`

TC Client pegasus-tc-client

We need to map our declared transformations (preprocess, findrange, and analyze) from the example DAX above to a simple "mock application" name "keg" ("canonical example for the grid") which reads input files designated by arguments, writes them back onto output files, and produces on `STDOUT` a summary of where and when it was run. Keg ships with Pegasus in the `bin` directory. Run `keg` on the command line to see how it works.

```
$ keg -o /dev/fd/1
```

```
Timestamp Today: 20040624T054607-05:00 (1088073967.418;0.022)
Applicationname: keg @ 10.10.0.11 (VPN)
Current Workdir: /home/unique-name
Systemenvironm.: i686-Linux 2.4.18-3
Processor Info.: 1 x Pentium III (Coppermine) @ 797.425
Output Filename: /dev/fd/1
```

Now we need to map all 3 transformations onto the "keg" executable. We place these mappings in our File transformation catalog for site `clus1`.

Note

In earlier version of Pegasus users had to define entries for Pegasus executables such as `transfer`, `replica client`, `dirmanager`, etc on each site as well as site "local". This is no longer required. Pegasus versions 2.0 and later automatically pick up the paths for these binaries from the environment profile `PEGASUS_HOME` set in the site catalog for each site.

A single entry needs to be on one line. The above example is just formatted for convenience.

Alternatively you can also use the pegasus-tc-client to add entries to any implementation of the transformation catalog. The following example shows the addition the last entry in the File based transformation catalog.

```
$ pegasus-tc-client -Dpegasus.catalog.transformation=Text \
-Dpegasus.catalog.transformation.file=$HOME/tc -a -r clus1 -l black::analyze:1.0 \
-p gsiftp://clus1.com/opt/nfs/vdt/pegasus/bin/keg -t STAGEABLE -s INTEL32::LINUX \
-e ENV::KEY3="VALUE3"
```

```
2007.07.11 16:12:03.712 PDT: [INFO] Added tc entry sucessfully
```

To verify if the entry was correctly added to the transformation catalog you can use the pegasus-tc-client to query.

```
$ pegasus-tc-client -Dpegasus.catalog.transformation=File \
-Dpegasus.catalog.transformation.file=$HOME/tc -q -P -l black::analyze:1.0
```

#RESID	LTX	PFN	TYPE	SYSINFO
clus1	black::analyze:1.0	gsiftp://clus1.com/opt/nfs/vdt/pegasus/bin/keg		
	STAGEABLE	INTEL32::LINUX		

TC Converter Client pegasus-tc-converter

Pegasus 3.0 by default now parses a file based multiline textual format of a Transformation Catalog. The new Text format is explained in detail in the chapter on Catalogs.

Pegasus 3.0 comes with a pegasus-tc-converter that will convert users old transformation catalog (File) to the Text format. Sample usage is given below.

```
$ pegasus-tc-converter -i sample.tc.data -I File -o sample.tc.text -O Text
```

```
2010.11.22 12:53:16.661 PST: Successfully converted Transformation Catalog from File to Text
2010.11.22 12:53:16.666 PST: The output transformation catalog is in file /lfs1/software/install/
pegasus/pegasus-3.0.0cvs/etc/sample.tc.text
```

To use the converted transformation catalog, in the properties do the following:

1. unset pegasus.catalog.transformation or set pegasus.catalog.transformation to Text
2. point pegasus.catalog.transformation.file to the converted transformation catalog

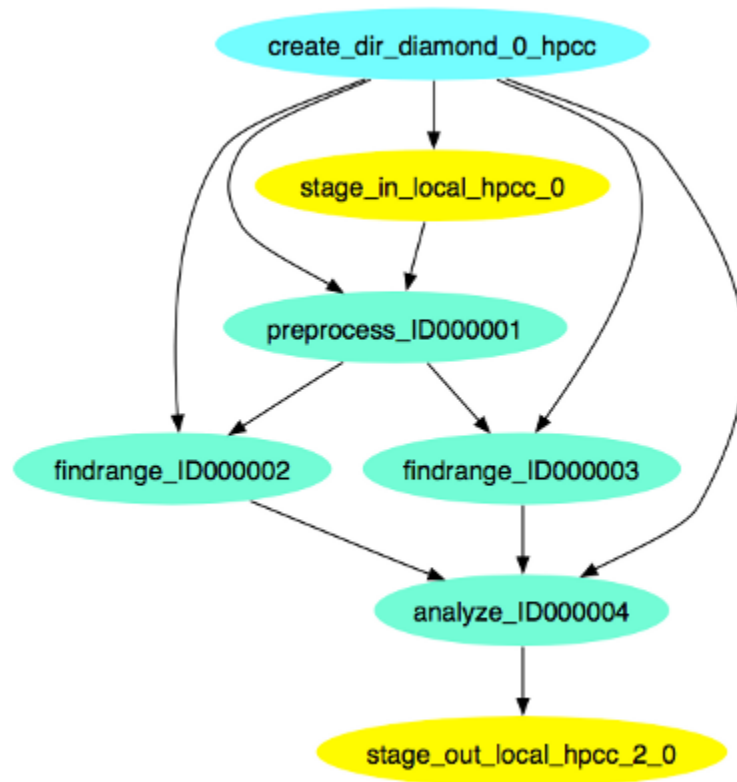

Chapter 5. Running Workflows

Executable Workflows (DAG)

The DAG is an executable (concrete) workflow that can be executed over a variety of resources. When the workflow tasks are mapped to multiple resources that do not share a file system, explicit nodes are added to the workflow for orchestrating data transfer between the tasks.

When you take the DAX workflow created in Creating Workflows, and plan it for a single remote grid execution, here a site with handle **hpcc**, and plan the workflow without clean-up nodes, the following concrete workflow is built:

Figure 5.1. Black Diamond DAG

Planning augments the original abstract workflow with ancillary tasks to facilitate the proper execution of the workflow. These tasks include:

- the creation of remote working directories. These directories typically have name that seeks to avoid conflicts with other simultaneously running similar workflows. Such tasks use a job prefix of `create_dir`.
- the stage-in of input files before any task which requires these files. Any file consumed by a task needs to be staged to the task, if it does not already exist on that site. Such tasks use a job prefix of `stage_in`. If multiple files from various sources need to be transferred, multiple stage-in jobs will be created. Additional advanced options permit to control the size and number of these jobs, and whether multiple compute tasks can share stage-in jobs.
- the original DAX job is concretized into a compute task in the DAG. Compute jobs are a concatenation of the job's **name** and **id** attribute from the DAX file.
- the stage-out of data products to a collecting site. Data products with their **transfer** flag set to `false` will not be staged to the output site. However, they may still be eligible for staging to other, dependent tasks. Stage-out tasks use a job prefix of `stage_out`.

- If compute jobs run at different sites, an intermediary staging task with prefix `stage_inter` is inserted between the compute jobs in the workflow, ensuring that the data products of the parent are available to the child job.
- the registration of data products in a replica catalog. Data products with their **register** flag set to `false` will not be registered.
- the clean-up of transient files and working directories. These steps can be omitted with the **--no-cleanup** option to the planner.

The "Reference Manual" Chapter details more about when and how staging nodes are inserted into the workflow.

The DAG will be found in file `diamond-0.dag`, constructed from the **name** and **index** attributes found in the root element of the DAX file.

```

#####
# End of DAG
#####
```

The DAG file declares all jobs and links them to a Condor submit file that describes the planned, concrete job. In the same directory as the DAG file are all Condor submit files for the jobs from the picture plus a number of additional helper files.

The various instructions that can be put into a DAG file are described in Condor's DAGMAN documentation [http://www.cs.wisc.edu/condor/manual/v7.5/2_10DAGMan_Applications.html]. The constituents of the submit directory are described in the "Submit Directory Details" chapter

Mapping Refinement Steps

During the mapping process, the abstract workflow undergoes a series of refinement steps that converts it to an executable form.

Data Reuse

The abstract workflow after parsing is optionally handed over to the Data Reuse Module. The Data Reuse Algorithm in Pegasus attempts to prune all the nodes in the abstract workflow for which the output files exist in the Replica Catalog. It also attempts to cascade the deletion to the parents of the deleted node for e.g if the output files for the leaf nodes are specified, Pegasus will prune out all the workflow as the output files in which a user is interested in already exist in the Replica Catalog.

The Data Reuse Algorithm works in two passes

First Pass - Determine all the jobs whose output files exist in the Replica Catalog. An output file with the transfer flag set to false is treated equivalent to the file existing in the Replica Catalog, if the output file is not an input to any of the children of the job X.

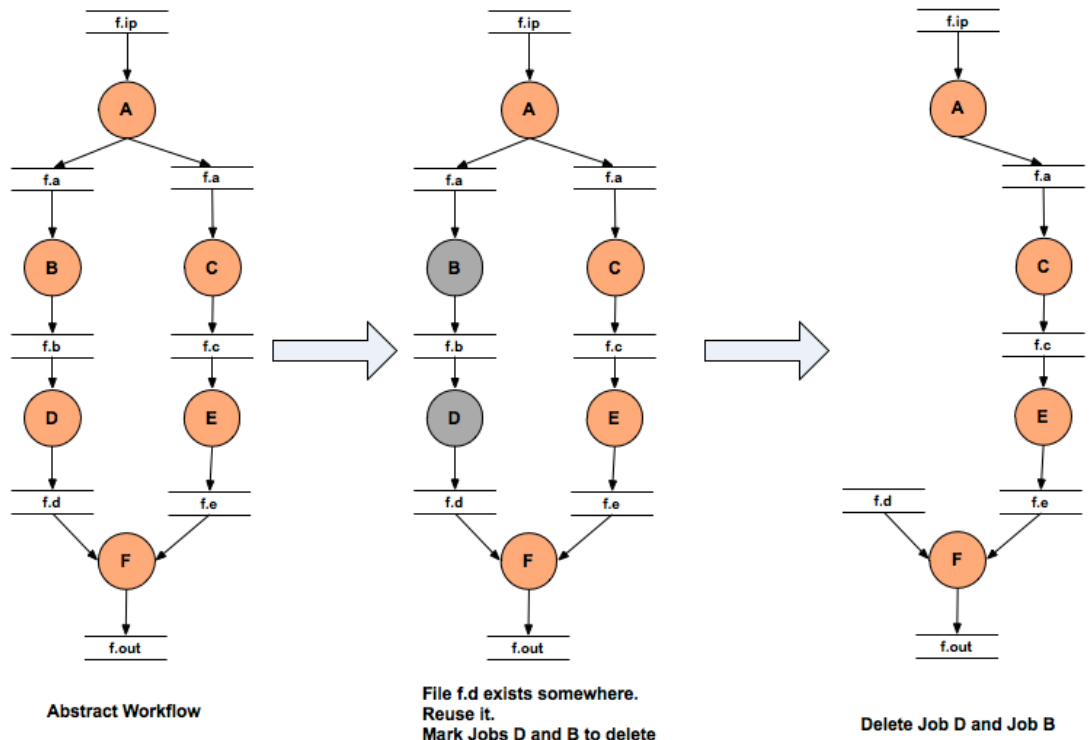

Second Pass - The algorithm removes the job whose output files exist in the Replica Catalog and tries to cascade the deletion upwards to the parent jobs. We start the breadth first traversal of the workflow bottom up.

```
( It is already marked for deletion in Pass 1
OR
  ( ALL of it's children have been marked for deletion
  AND
    Node's output files have transfer flags set to false
  )
)
```

Tip

The Data Reuse Algorithm can be disabled by passing the **--force** option to pegasus-plan.

Figure 5.2. Workflow Data Reuse

Site Selection

The abstract workflow is then handed over to the Site Selector module where the abstract jobs in the pruned workflow are mapped to the various sites passed by a user. The target sites for planning are specified on the command line using the `--sites` option to `pegasus-plan`. If not specified, then Pegasus picks up all the sites in the Site Catalog as candidate sites. Pegasus will map a compute job to a site only if Pegasus can

- find an **INSTALLED** executable on the site
- OR find a **STAGEABLE** executable that can be staged to the site as part of the workflow execution.

Pegasus supports variety of site selectors with Random being the default

- **Random**

The jobs will be randomly distributed among the sites that can execute them.

- **RoundRobin**

The jobs will be assigned in a round robin manner amongst the sites that can execute them. Since each site cannot execute every type of job, the round robin scheduling is done per level on a sorted list. The sorting is on the basis of the number of jobs a particular site has been assigned in that level so far. If a job cannot be run on the first site in the queue (due to no matching entry in the transformation catalog for the transformation referred to by the job), it goes to the next one and so on. This implementation defaults to classic round robin in the case where all the jobs in the workflow can run on all the sites.

- **Group**

Group of jobs will be assigned to the same site that can execute them. The use of the **PEGASUS profile key group** in the DAX, associates a job with a particular group. The jobs that do not have the profile key associated with them, will be put in the default group. The jobs in the default group are handed over to the "Random" Site Selector for scheduling.

- **Heft**

A version of the HEFT processor scheduling algorithm is used to schedule jobs in the workflow to multiple grid sites. The implementation assumes default data communication costs when jobs are not scheduled on to the same site. Later on this may be made more configurable.

The runtime for the jobs is specified in the transformation catalog by associating the **pegasus profile key runtime** with the entries.

The number of processors in a site is picked up from the attribute **idle-nodes** associated with the vanilla jobmanager of the site in the site catalog.

- **NonJavaCallout**

Pegasus will callout to an external site selector. In this mode a temporary file is prepared containing the job information that is passed to the site selector as an argument while invoking it. The path to the site selector is specified by setting the property `pegasus.site.selector.path`. The environment variables that need to be set to run the site selector can be specified using the properties with a `pegasus.site.selector.env.` prefix. The temporary file contains information about the job that needs to be scheduled. It contains key value pairs with each key value pair being on a new line and separated by a `=`.

The following pairs are currently generated for the site selector temporary file that is generated in the NonJava-Callout.

Table 5.1. Table 1: Key Value Pairs that are currently generated for the site selector temporary file that is generated in the NonJavaCallout.

Key	Value
-----	-------

version	is the version of the site selector api,currently 2.0.
transformation	is the fully-qualified definition identifier for the transformation (TR) namespace::name:version.
derivation	is the fully qualified definition identifier for the derivation (DV), namespace::name:version.
job.level	is the job's depth in the tree of the workflow DAG.
job.id	is the job's ID, as used in the DAX file.
resource.id	is a pool handle, followed by whitespace, followed by a gridftp server. Typically, each gridftp server is enumerated once, so you may have multiple occurrences of the same site. There can be multiple occurrences of this key.
input.lfn	is an input LFN, optionally followed by a whitespace and file size. There can be multiple occurrences of this key,one for each input LFN required by the job.
wf.name	label of the dax, as found in the DAX's root element. wf.index is the DAX index, that is incremented for each partition in case of deferred planning.
wf.time	is the mtime of the workflow.
wf.manager	is the name of the workflow manager being used .e.g condor
vo.name	is the name of the virtual organization that is running this workflow. It is currently set to NONE
vo.group	unused at present and is set to NONE.

Tip

The site selector to use for site selection can be specified by setting the property **pegasus.selector.site**

Figure 5.3. Workflow Site Selection

Job Clustering

After site selection, the workflow is optionally handed for to the job clustering module, which clusters jobs that are scheduled to the same site. Clustering is usually done on short running jobs in order to reduce the remote execution overheads associated with a job. Clustering is described in detail in the Reference Manual chapter.

Tip

The job clustering is turned on by passing the **--cluster** option to `pegasus-plan`.

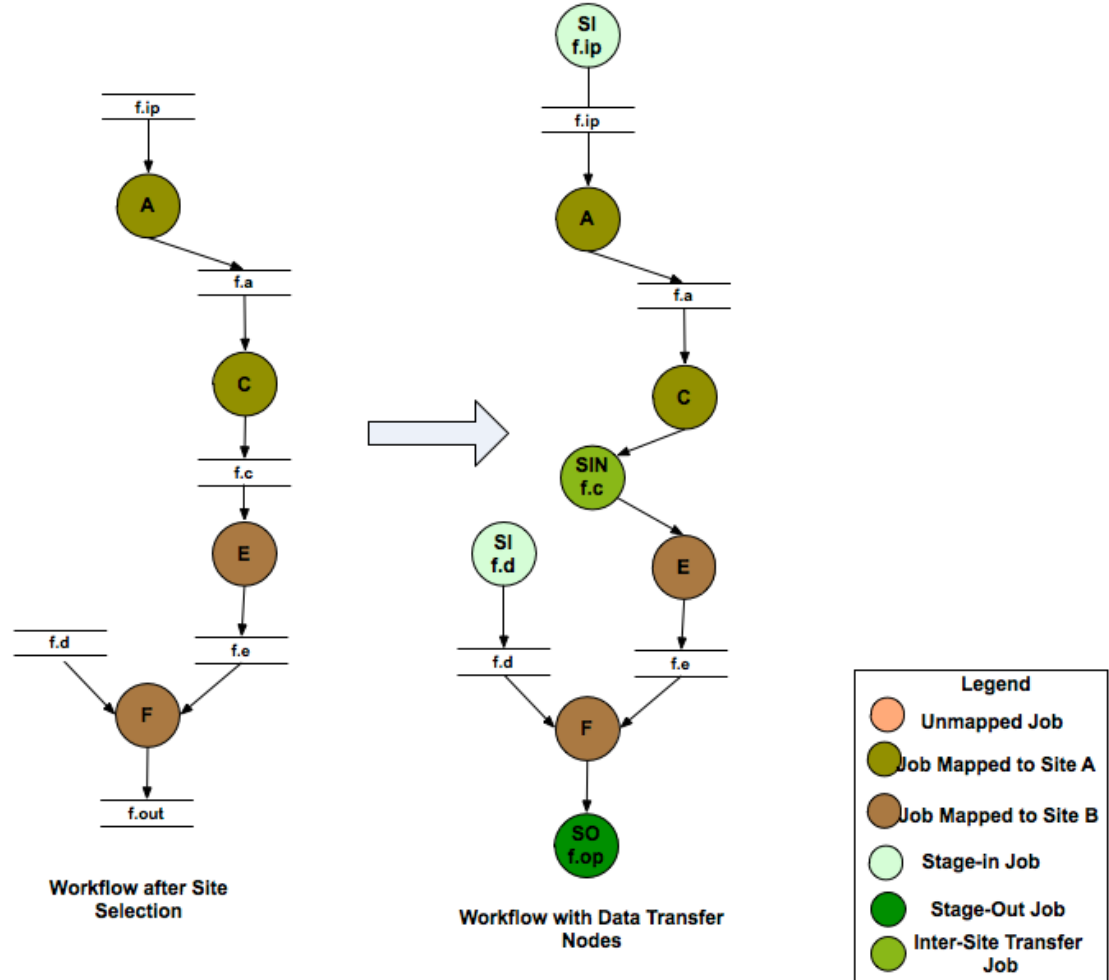

Addition of Data Transfer and Registration Nodes

After job clustering, the workflow is handed to the Data Transfer module that adds data stage-in , inter site and stage-out nodes to the workflow. Data Stage-in Nodes transfer input data required by the workflow from the locations specified in the Replica Catalog to a directory on the staging site associated with the job. The staging site for a job is the execution site if running in a sharedfs mode, else it is the one specified by **--staging-site** option to the planner. In case, multiple locations are specified for the same input file, the location from where to stage the data is selected using a **Replica Selector** . Replica Selection is described in detail in the Replica Selection section of the Reference Manual. More details about staging site can be found in the data staging configuration chapter.

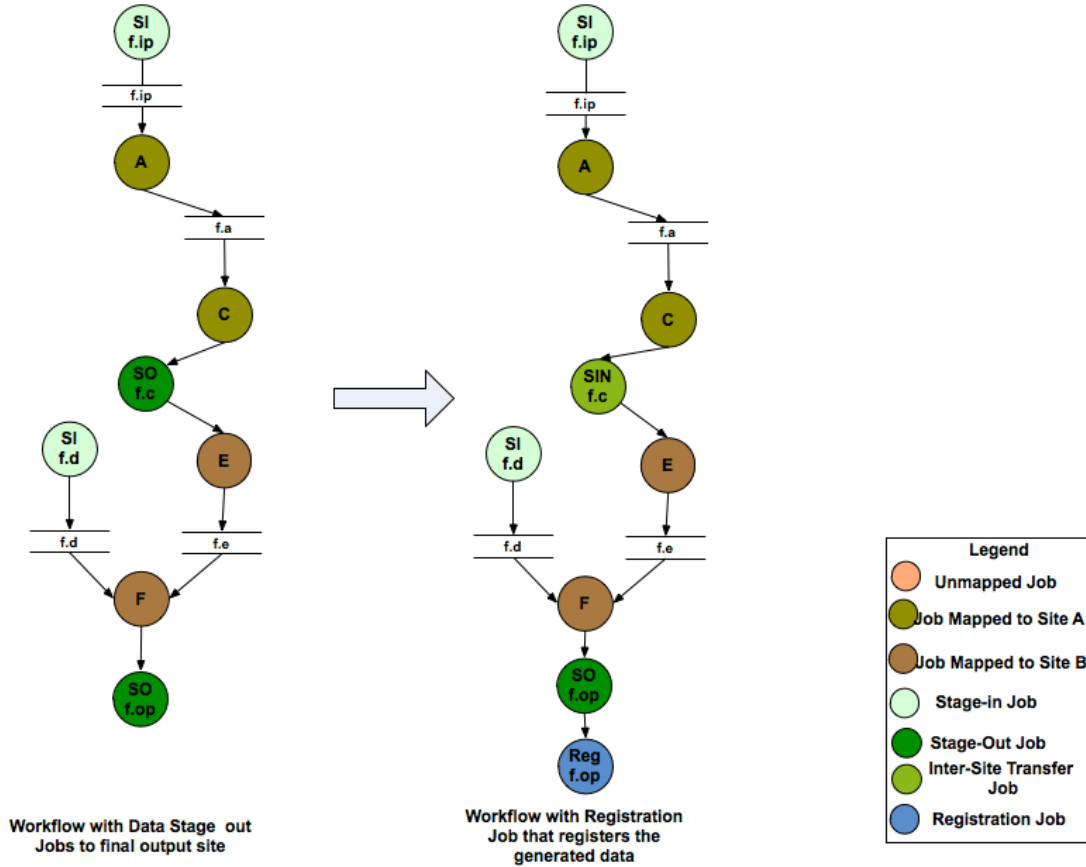

The process of adding the data stage-in and data stage-out nodes is handled by Transfer Refiners. All data transfer jobs in Pegasus are executed using **pegasus-transfer** . The pegasus-transfer client is a python based wrapper around various transfer clients like `globus-url-copy`, `s3cmd`, `irods-transfer`, `scp`, `wget`, `cp`, `ln` . It looks at source and destination url and

figures out automatically which underlying client to use. pegasus-transfer is distributed with the PEGASUS and can be found in the bin subdirectory . Pegasus Transfer Refiners are described in the detail in the Transfers section of the Reference Manual. The default transfer refiner that is used in Pegasus is the **Bundle** Transfer Refiner, that bundles data stage-in nodes and data stage-out nodes on the basis of certain pegasus profile keys associated with the workflow.

Figure 5.4. Addition of Data Transfer Nodes to the Workflow

Data Registration Nodes may also be added to the final executable workflow to register the location of the output files on the final output site back in the Replica Catalog . An output file is registered in the Replica Catalog if the register flag for the file is set to true in the DAX.

Figure 5.5. Addition of Data Registration Nodes to the Workflow

The data staged-in and staged-out from a directory that is created on the head node by a create dir job in the workflow. In the vanilla case, the directory is visible to all the worker nodes and compute jobs are launched in this directory on the shared filesystem. In the case where there is no shared filesystem, users can turn on worker node execution, where the data is staged from the head node directory to a directory on the worker node filesystem. This feature will be refined further for Pegasus 3.1. To use it with Pegasus 3.0 send email to [pegasus-support at isi.edu](mailto:pegasus-support@isi.edu).

Tip

The replica selector to use for replica selection can be specified by setting the property `pegasus.selector.replica`

Addition of Create Dir and Cleanup Jobs

After the data transfer nodes have been added to the workflow, Pegasus adds a create dir jobs to the workflow. Pegasus usually, creates one workflow specific directory per compute site, that is on the staging site associated with the job. In the case of shared shared filesystem setup, it is a directory on the shared filesystem of the compute site. In case of shared filesystem setup, this directory is visible to all the worker nodes and that is where the data is staged-in by the data stage-in jobs.

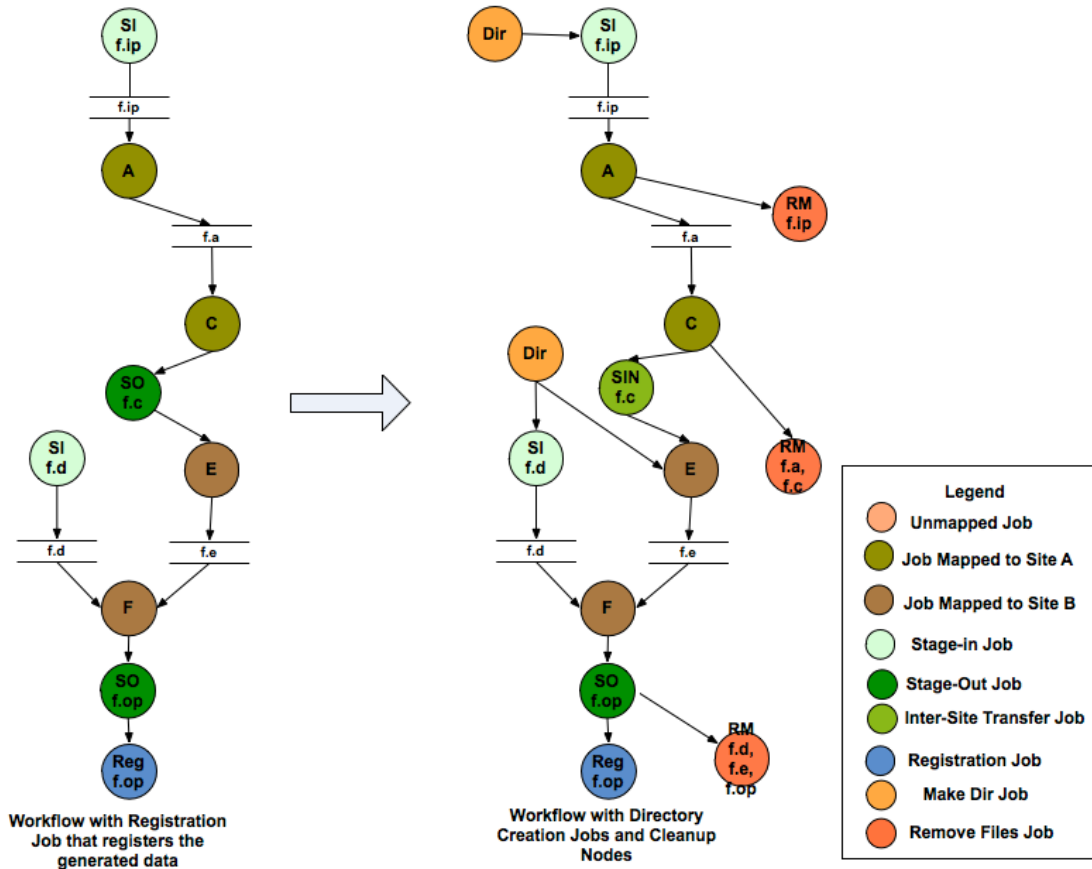

The staging site for a job is the execution site if running in a sharedfs mode, else it is the one specified by `--staging-site` option to the planner. More details about staging site can be found in the data staging configuration chapter.

After addition of the create dir jobs, the workflow is optionally handed to the cleanup module. The cleanup module adds cleanup nodes to the workflow that remove data from the directory on the shared filesystem when it is no longer required by the workflow. This is useful in reducing the peak storage requirements of the workflow.

Tip

The addition of the cleanup nodes to the workflow can be disabled by passing the **--nocleanup** option to pegasus-plan.

Figure 5.6. Addition of Directory Creation and File Removal Jobs

Tip

Users can specify the maximum number of cleanup jobs added per level by specifying the property **pegasus.file.cleanup.clusters.num** in the properties.

Code Generation

The last step of refinement process, is the code generation where Pegasus writes out the executable workflow in a form understandable by the underlying workflow executor. At present Pegasus supports the following code generators

1. Condor

This is the default code generator for Pegasus . This generator generates the executable workflow as a Condor DAG file and associated job submit files. The Condor DAG file is passed as input to Condor DAGMan for job execution.

2. Shell

This Code Generator generates the executable workflow as a shell script that can be executed on the submit host. While using this code generator, all the jobs should be mapped to site local i.e specify **--sites local** to pegasus-plan.

Tip

To use the Shell code Generator set the property `pegasus.code.generator` Shell

Figure 5.7. Final Executable Workflow

Data Staging Configuration

Pegasus can be broadly setup to run workflows in the following configurations

- **Shared File System**

This setup applies to where the head node and the worker nodes of a cluster share a filesystem. Compute jobs in the workflow run in a directory on the shared filesystem.

- **NonShared FileSystem**

This setup applies to where the head node and the worker nodes of a cluster don't share a filesystem. Compute jobs in the workflow run in a local directory on the worker node

- **Condor Pool Without a shared filesystem**

This setup applies to a condor pool where the worker nodes making up a condor pool don't share a filesystem. All data IO is achieved using Condor File IO. This is a special case of the non shared filesystem setup, where instead of using pegasus-transfer to transfer input and output data, Condor File IO is used.

For the purposes of data configuration various sites, and directories are defined below.

1. **Submit Host**

The host from where the workflows are submitted . This is where Pegasus and Condor DAGMan are installed. This is referred to as the "**local**" site in the site catalog .

2. **Compute Site**

The site where the jobs mentioned in the DAX are executed. There needs to be an entry in the Site Catalog for every compute site. The compute site is passed to pegasus-plan using **--sites** option

3. **Staging Site**

A site to which the separate transfer jobs in the executable workflow (jobs with stage_in , stage_out and stage_inter prefixes that Pegasus adds using the transfer refiners) stage the input data to and the output data from to transfer to the final output site. Currently, the staging site is always the compute site where the jobs execute.

4. **Output Site**

The output site is the final storage site where the users want the output data from jobs to go to. The output site is passed to pegasus-plan using the **--output** option. The stageout jobs in the workflow stage the data from the staging site to the final storage site.

5. **Input Site**

The site where the input data is stored. The locations of the input data are catalogued in the Replica Catalog, and the pool attribute of the locations gives us the site handle for the input site.

6. **Workflow Execution Directory**

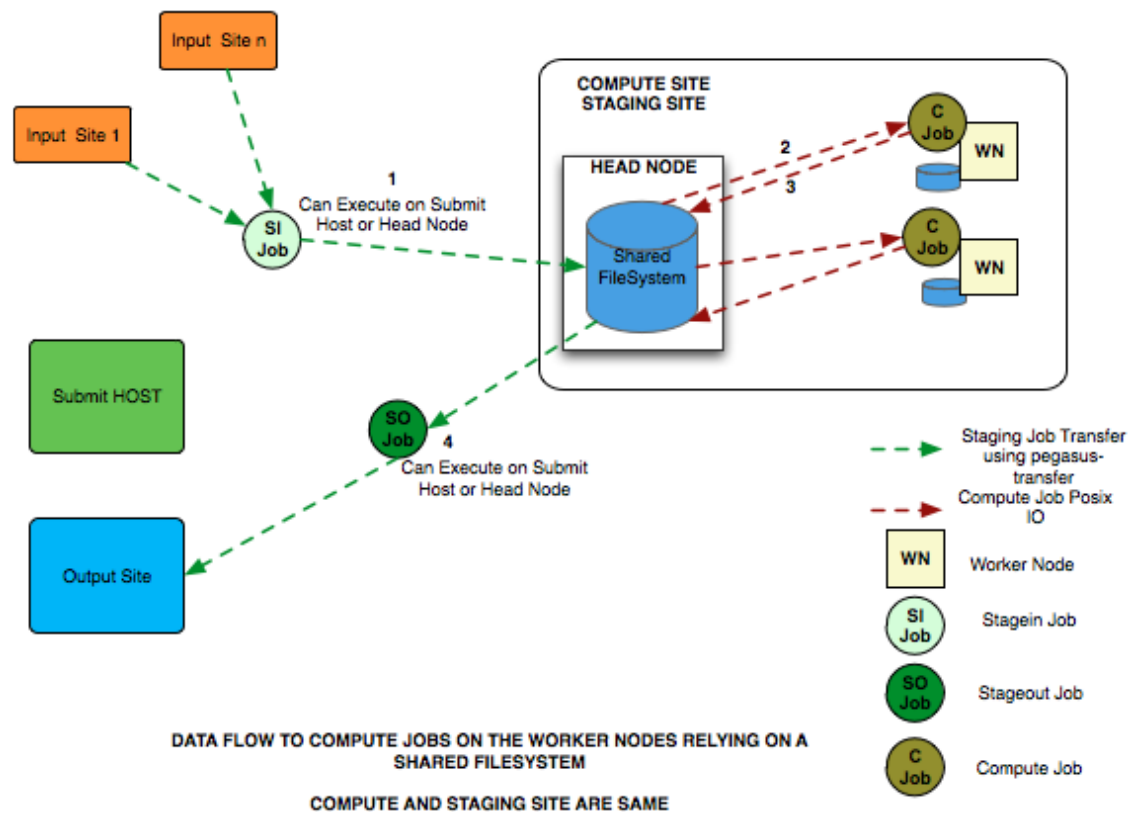

This is the directory created by the create dir jobs in the executable workflow on the Staging Site. This is a directory per workflow per staging site. Currently, the Staging site is always the Compute Site.

7. **Worker Node Directory**

This is the directory created on the worker nodes per job usually by the job wrapper that launches the job.

Shared File System

By default Pegasus is setup to run workflows in the shared file system setup, where the worker nodes and the head node of a cluster share a filesystem.

Figure 5.8. Shared File System Setup

The data flow is as follows in this case

1. Stagein Job executes (either on Submit Host or Head Node) to stage in input data from Input Sites (1---n) to a workflow specific execution directory on the shared filesystem.
2. Compute Job starts on a worker node in the workflow execution directory. Accesses the input data using Posix IO
3. Compute Job executes on the worker node and writes out output data to workflow execution directory using Posix IO
4. Stageout Job executes (either on Submit Host or Head Node) to stage out output data from the workflow specific execution directory to a directory on the final output site.

Tip

Set `pegasus.data.configuration` to `sharedfs` to run in this configuration.

Non Shared Filesystem

In this setup , Pegasus runs workflows on local file-systems of worker nodes with the the worker nodes not sharing a filesystem. The data transfers happen between the worker node and a staging / data coordination site. The staging site server can be a file server on the head node of a cluster or can be on a separate machine.

Setup

- compute and staging site are the different
- head node and worker nodes of compute site don't share a filesystem

- Input Data is staged from remote sites.
- Remote Output Site i.e site other than compute site. Can be submit host.

Figure 5.9. Non Shared Filesystem Setup

The data flow is as follows in this case

1. Stagein Job executes (either on Submit Host or on staging site) to stage in input data from Input Sites (1---n) to a workflow specific execution directory on the staging site.
2. Compute Job starts on a worker node in a local execution directory. Accesses the input data using pegasus transfer to transfer the data from the staging site to a local directory on the worker node
3. The compute job executes in the worker node, and executes on the worker node.
4. The compute Job writes out output data to the local directory on the worker node using Posix IO
5. Output Data is pushed out to the staging site from the worker node using pegasus-transfer.
6. Stageout Job executes (either on Submit Host or staging site) to stage out output data from the workflow specific execution directory to a directory on the final output site.

In this case, the compute jobs are wrapped as PegasusLite instances.

This mode is especially useful for running in the cloud environments where you don't want to setup a shared filesystem between the worker nodes. Running in that mode is explained in detail here.

Tip

Set **pegasus.data.configuration** to **nonsharedfs** to run in this configuration. The staging site can be specified using the **--staging-site** option to pegasus-plan.

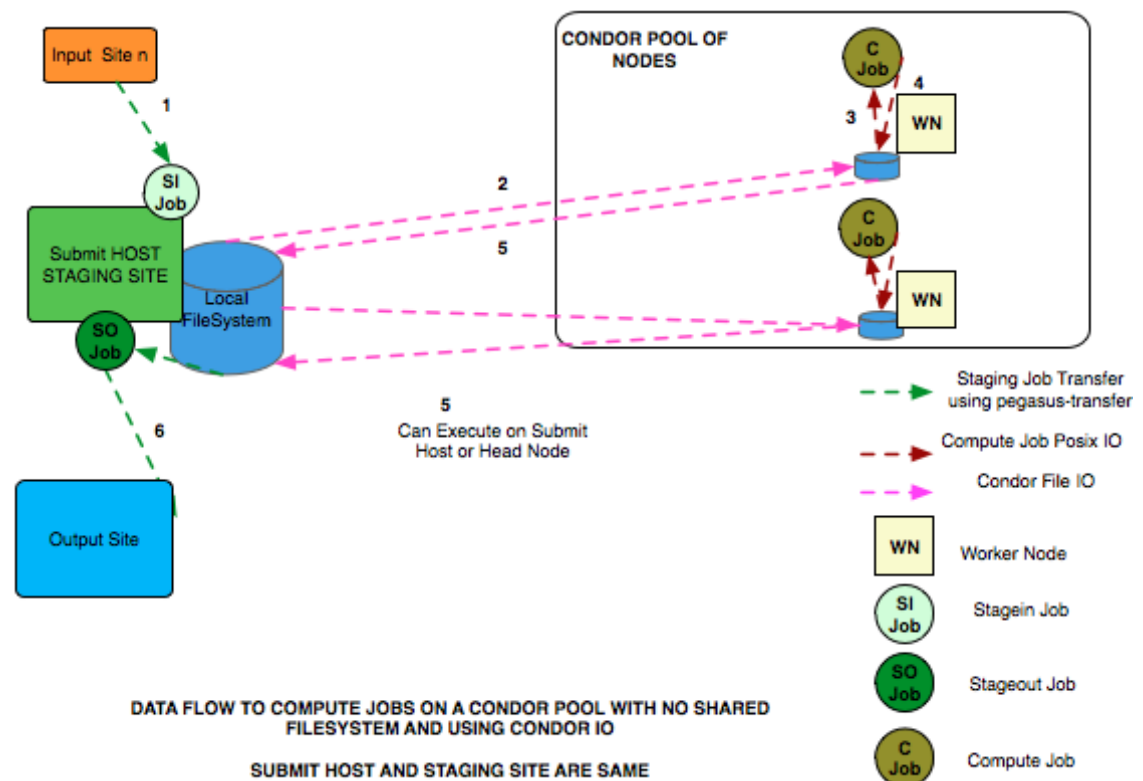

Condor Pool Without a Shared Filesystem

This setup applies to a condor pool where the worker nodes making up a condor pool don't share a filesystem. All data IO is achieved using Condor File IO. This is a special case of the non shared filesystem setup, where instead of using pegasus-transfer to transfer input and output data, Condor File IO is used.

Setup

- Submit Host and staging site are same
- head node and worker nodes of compute site don't share a filesystem
- Input Data is staged from remote sites.
- Remote Output Site i.e site other than compute site. Can be submit host.

Figure 5.10. Condor Pool Without a Shared Filesystem

The data flow is as follows in this case

1. Stagein Job executes on the submit host to stage in input data from Input Sites (1---n) to a workflow specific execution directory on the submit host
2. Compute Job starts on a worker node in a local execution directory. Before the compute job starts, Condor transfers the input data for the job from the workflow execution directory on the submit host to the local execution directory on the worker node.
3. The compute job executes in the worker node, and executes on the worker node.
4. The compute Job writes out output data to the local directory on the worker node using Posix IO
5. When the compute job finishes, Condor transfers the output data for the job from the local execution directory on the worker node to the workflow execution directory on the submit host.

6. Stageout Job executes (either on Submit Host or staging site) to stage out output data from the workflow specific execution directory to a directory on the final output site.

In this case, the compute jobs are wrapped as PegasusLite instances.

This mode is especially useful for running in the cloud environments where you don't want to setup a shared filesystem between the worker nodes. Running in that mode is explained in detail here.

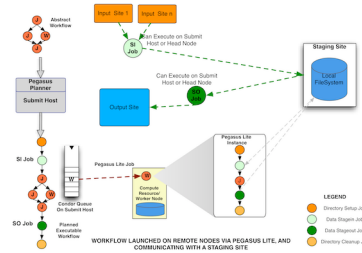

Tip

Set `pegasus.data.configuration` to `condorio` to run in this configuration. In this mode, the staging site is automatically set to site `local`

PegasusLite

Starting Pegasus 4.0 , all compute jobs (single or clustered jobs) that are executed in a non shared filesystem setup, are executed using lightweight job wrapper called PegasusLite.

Figure 5.11. Workflow Running in NonShared Filesystem Setup with PegasusLite launching compute jobs

When PegasusLite starts on a remote worker node to run a compute job , it performs the following actions:

1. Discovers the best run-time directory based on space requirements and create the directory on the local filesystem of the worker node to execute the job.
2. Prepare the node for executing the unit of work. This involves discovering whether the pegasus worker tools are already installed on the node or need to be brought in.
3. Use pegasus-transfer to stage in the input data to the runtime directory (created in step 1) on the remote worker node.
4. Launch the compute job.
5. Use pegasus-transfer to stage out the output data to the data coordination site.
6. Remove the directory created in Step 1.

Pegasus-Plan

pegasus-plan is the main executable that takes in the abstract workflow (DAX) and generates an executable workflow (usually a Condor DAG) by querying various catalogs and performing several refinement steps. Before users can run pegasus plan the following needs to be done:

1. Populate the various catalogs
 - a. **Replica Catalog**

The Replica Catalog needs to be catalogued with the locations of the input files required by the workflows. This can be done by using pegasus-rc-client (See the Replica section of Creating Workflows).

- b. **Transformation Catalog**

The Transformation Catalog needs to be catalogued with the locations of the executables that the workflows will use. This can be done by using `pegasus-tc-client` (See the Transformation section of Creating Workflows).

c. Site Catalog

The Site Catalog needs to be catalogued with the site layout of the various sites that the workflows can execute on. A site catalog can be generated for OSG by using the client `pegasus-sc-client` (See the Site section of the Creating Workflows).

2. Configure Properties

After the catalogs have been configured, the user properties file need to be updated with the types and locations of the catalogs to use. These properties are described in the **basic.properties** files in the **etc** sub directory (see the Properties section of theReference chapter).

The basic properties that need to be set usually are listed below:

Table 5.2. Table2: Basic Properties that need to be set

<code>pegasus.catalog.replica</code>
<code>pegasus.catalog.replica.file</code> <code>pegasus.catalog.replica.url</code>
<code>pegasus.catalog.transformation</code>
<code>pegasus.catalog.transformation.file</code>
<code>pegasus.catalog.site.file</code>

To execute `pegasus-plan` user usually requires to specify the following options:

1. **--dax** the path to the DAX file that needs to be mapped.
2. **--dir** the base directory where the executable workflow is generated
3. **--sites** comma separated list of execution sites.
4. **--output** the output site where to transfer the materialized output files.
5. **--submit** boolean value whether to submit the planned workflow for execution after planning is done.

Basic Properties

This is the reference guide to the basic properties regarding the Pegasus Workflow Planner, and their respective default values. Please refer to the advanced properties guide to know about all the properties that a user can use to configure the Pegasus Workflow Planner. Please note that the values rely on proper capitalization, unless explicitly noted otherwise.

Some properties rely with their default on the value of other properties. As a notation, the curly braces refer to the value of the named property. For instance, `${pegasus.home}` means that the value depends on the value of the `pegasus.home` property plus any noted additions. You can use this notation to refer to other properties, though the extent of the substitutions are limited. Usually, you want to refer to a set of the standard system properties. Nesting is not allowed. Substitutions will only be done once.

There is a priority to the order of reading and evaluating properties. Usually one does not need to worry about the priorities. However, it is good to know the details of when which property applies, and how one property is able to overwrite another. The following is a mutually exclusive list (highest priority first) of property file locations.

1. **--conf** option to the tools. Almost all of the clients that use properties have a **--conf** option to specify the property file to pick up.
2. `submit-dir/pegasus.xxxxxxx.properties` file. All tools that work on the submit directory (i.e after pegasus has planned a workflow) pick up the `pegasus.xxxxxx.properties` file from the submit directory. The location for the `pegasus.xxxxxxx.properties` is picked up from the `braindump` file.

3. The properties defined in the user property file `$(user.home)/.pegasusrc` have lowest priority.

Commandline properties have the highest priority. These override any property loaded from a property file. Each commandline property is introduced by a `-D` argument. Note that these arguments are parsed by the shell wrapper, and thus the `-D` arguments must be the first arguments to any command. Commandline properties are useful for debugging purposes.

From Pegasus 3.1 release onwards, support has been dropped for the following properties that were used to signify the location of the properties file

- `pegasus.properties`
- `pegasus.user.properties`

The following example provides a sensible set of properties to be set by the user property file. These properties use mostly non-default settings. It is an example only, and will not work for you:

```
pegasus.catalog.replica      File
pegasus.catalog.replica.file ${pegasus.home}/etc/sample.rc.data
pegasus.catalog.replica      Regex
pegasus.catalog.replica.file ${pegasus.home}/etc/sample.rc.data
pegasus.catalog.transformation Text
pegasus.catalog.transformation.file ${pegasus.home}/etc/sample.tc.text
pegasus.catalog.site.file    ${pegasus.home}/etc/sample.sites.xml
```

If you are in doubt which properties are actually visible, pegasus during the planning of the workflow dumps all properties after reading and prioritizing in the submit directory in a file with the suffix properties.

pegasus.home

Systems:	all
Type:	directory location string
Default:	"\$PEGASUS_HOME"

The property `pegasus.home` cannot be set in the property file. This property is automatically set up by the pegasus clients internally by determining the installation directory of pegasus. Knowledge about this property is important for developers who want to invoke PEGASUS JAVA classes without the shell wrappers.

Catalog Properties

Replica Catalog

pegasus.catalog.replica

System:	Pegasus
Since:	2.0
Type:	enumeration
Value[0]:	RLS
Value[1]:	LRC
Value[2]:	JDBCRC
Value[3]:	File
Value[4]:	Directory
Value[5]:	MRC
Value[6]:	Regex

Default:

| RLS

Pegasus queries a Replica Catalog to discover the physical filenames (PFN) for input files specified in the DAX. Pegasus can interface with various types of Replica Catalogs. This property specifies which type of Replica Catalog to use during the planning process.

RLS RLS (Replica Location Service) is a distributed replica catalog, which ships with GT4. There is an index service called Replica Location Index (RLI) to which 1 or more Local Replica Catalog (LRC) report. Each LRC can contain all or a subset of mappings. In this mode, Pegasus queries the central RLI to discover in which LRC's the mappings for a LFN reside. It then queries the individual LRC's for the PFN's. To use RLS, the user additionally needs to set the property `pegasus.catalog.replica.url` to specify the URL for the RLI to query. Details about RLS can be found at <http://www.globus.org/toolkit/data/rls/>

LRC If the user does not want to query the RLI, but directly a single Local Replica Catalog. To use LRC, the user additionally needs to set the property `pegasus.catalog.replica.url` to specify the URL for the LRC to query. Details about RLS can be found at <http://www.globus.org/toolkit/data/rls/>

JDBCRC In this mode, Pegasus queries a SQL based replica catalog that is accessed via JDBC. The sql schema's for this catalog can be found at `$PEGASUS_HOME/sql` directory. To use JDBCRC, the user additionally needs to set the following properties

1. `pegasus.catalog.replica.db.url`
2. `pegasus.catalog.replica.db.user`
3. `pegasus.catalog.replica.db.password`

File In this mode, Pegasus queries a file based replica catalog. It is neither transactionally safe, nor advised to use for production purposes in any way. Multiple concurrent access to the File will end up clobbering the contents of the file. The site attribute should be specified whenever possible. The attribute key for the site attribute is "pool".

The LFN may or may not be quoted. If it contains linear whitespace, quotes, backslash or an equality sign, it must be quoted and escaped. Ditto for the PFN. The attribute key-value pairs are separated by an equality sign without any whitespaces. The value may be in quoted. The LFN sentiments about quoting apply.

```
LFN PFN
LFN PFN a=b [...]
LFN PFN a="b" [...]
"LFN w/LWS" "PFN w/LWS" [...]
```

To use File, the user additionally needs to specify `pegasus.catalog.replica.file` property to specify the path to the file based RC.

Regex In this mode, Pegasus queries a file based replica catalog. It is neither transactionally safe, nor advised to use for production purposes in any way. Multiple concurrent access to the File will end up clobbering the contents of the file. The site attribute should be specified whenever possible. The attribute key for the site attribute is "pool".

The LFN may or may not be quoted. If it contains linear whitespace, quotes, backslash or an equality sign, it must be quoted and escaped. Ditto for the PFN. The attribute key-value pairs are separated by an equality sign without any whitespaces. The value may be in quoted. The LFN sentiments about quoting apply.

In addition users can specify regular expression based LFN's. A regular expression based entry should be qualified with an attribute named 'regex'. The attribute `regex` when set to true identifies the catalog entry as a regular expression based entry. Regular expressions should follow Java regular expression syntax.

For example, consider a replica catalog as shown below.

Entry 1 refers to an entry which does not use a regular expressions. This entry would only match a file named 'f.a', and nothing else. Entry 2 refers to an entry which uses a regular expression. In this entry f.a refers to files having name as f[any-character]a i.e. faa, f.a, f0a, etc.

```
f.a file:///Volumes/data/input/f.a pool="local"
f.a file:///Volumes/data/input/f.a pool="local" regex="true"
```

Regular expression based entries also support substitutions. For example, consider the regular expression based entry shown below.

Entry 3 will match files with name alpha.csv, alpha.txt, alpha.xml. In addition, values matched in the expression can be used to generate a PFN.

For the entry below if the file being looked up is alpha.csv, the PFN for the file would be generated as file:///Volumes/data/input/csv/alpha.csv. Similarly if the file being lookedup was alpha.xml, the PFN for the file would be generated as file:///Volumes/data/input/xml/alpha.xml i.e. The section [0], [1] will be replaced. Section [0] refers to the entire string i.e. alpha.csv. Section [1] refers to a partial match in the input i.e. csv, or txt, or xml. Users can utilize as many sections as they wish.

```
alpha\.(csv|txt|xml) file:///Volumes/data/input/[1]/[0] pool="local" regex="true"
```

To use File, the user additionally needs to specify pegasus.catalog.replica.file property to specify the path to the file based RC.

Directory

In this mode, Pegasus does a directory listing on an input directory to create the LFN to PFN mappings. The directory listing is performed recursively, resulting in deep LFN mappings. For example, if an input directory \$input is specified with the following structure

```
$input
$input/f.1
$input/f.2
$input/D1
$input/D1/f.3
```

Pegasus will create the mappings the following LFN PFN mappings internally

```
f.1 file://$input/f.1 pool="local"
f.2 file://$input/f.2 pool="local"
D1/f.3 file://$input/D2/f.3 pool="local"
```

pegasus-plan has --input-dir option that can be used to specify an input directory.

Users can optionally specify additional properties to configure the behavior of this implementation.

pegasus.catalog.replica.directory.site to specify a site attribute other than local to associate with the mappings.

pegasus.catalog.replica.directory.url.prefix to associate a URL prefix for the PFN's constructed. If not specified, the URL defaults to file://

MRC

In this mode, Pegasus queries multiple replica catalogs to discover the file locations on the grid. To use it set

```
pegasus.catalog.replica MRC
```

Each associated replica catalog can be configured via properties as follows.

The user associates a variable name referred to as [value] for each of the catalogs, where [value] is any legal identifier (concretely [A-Za-z][_A-Za-z0-9]*) For each associated replica catalogs the user specifies the following properties.

```

pegasus.catalog.replica.mrc.[value]      specifies the type of replica catalog.
pegasus.catalog.replica.mrc.[value].key  specifies a property name key for a
particular catalog

```

For example, if a user wants to query two lrc's at the same time he/she can specify as follows

```

pegasus.catalog.replica.mrc.lrc1 LRC
pegasus.catalog.replica.mrc.lrc2.url rls://sukhna
pegasus.catalog.replica.mrc.lrc2 LRC
pegasus.catalog.replica.mrc.lrc2.url rls://smarty

```

In the above example, lrc1, lrc2 are any valid identifier names and url is the property key that needed to be specified.

pegasus.catalog.replica.url

System:	Pegasus
Since:	2.0
Type:	URI string
Default:	(no default)

When using the modern RLS replica catalog, the URI to the Replica catalog must be provided to Pegasus to enable it to look up filenames. There is no default.

Site Catalog

pegasus.catalog.site.file

System:	Site Catalog
Since:	2.0
Type:	file location string
Default:	\${pegasus.home.sysconfdir}/sites.xml

Running things on the grid requires an extensive description of the capabilities of each compute cluster, commonly termed "site". This property describes the location of the file that contains such a site description. As the format is currently in flow, please refer to the userguide and Pegasus for details which format is expected.

Transformation Catalog

pegasus.catalog.transformation

System:	Transformation Catalog
Since:	2.0
Type:	enumeration
Value[0]:	Text
Value[1]:	File
Default:	Text
See also:	pegasus.catalog.transformation.file

Text In this mode, a multiline file based format is understood. The file is read and cached in memory. Any modifications, as adding or deleting, causes an update of the memory and hence to the file underneath. All queries are done against the memory representation.

The file sample.tc.text in the etc directory contains an example

Here is a sample textual format for transformation catalog containing one transformation on two sites

```
tr example::keg:1.0 {
#specify profiles that apply for all the sites for the transformation
#in each site entry the profile can be overridden
profile env "APP_HOME" "/tmp/karan"
profile env "JAVA_HOME" "/bin/app"
site isi {
profile env "me" "with"
profile condor "more" "test"
profile env "JAVA_HOME" "/bin/java.1.6"
pfn "/path/to/keg"
arch "x86"
os "linux"
osrelease "fc"
osversion "4"
type "INSTALLED"
site wind {
profile env "me" "with"
profile condor "more" "test"
pfn "/path/to/keg"
arch "x86"
os "linux"
osrelease "fc"
osversion "4"
type "STAGEABLE"
}
```

File THIS FORMAT IS DEPRECATED. WILL BE REMOVED IN COMING VERSIONS. USE pegasus-tc-converter to convert File format to Text Format. In this mode, a file format is understood. The file is read and cached in memory. Any modifications, as adding or deleting, causes an update of the memory and hence to the file underneath. All queries are done against the memory representation. The new TC file format uses 6 columns:

1. The resource ID is represented in the first column.
2. The logical transformation uses the colonized format ns::name:vs.
3. The path to the application on the system
4. The installation type is identified by one of the following keywords - all upper case: INSTALLED, STAGEABLE. If not specified, or **NULL** is used, the type defaults to INSTALLED.
5. The system is of the format ARCH::OS[:VER:GLIBC]. The following arch types are understood: "INTEL32", "INTEL64", "SPARCV7", "SPARCV9". The following os types are understood: "LINUX", "SUNOS", "AIX". If unset or **NULL**, defaults to INTEL32::LINUX.
6. Profiles are written in the format NS::KEY=VALUE,KEY2=VALUE;NS2::KEY3=VALUE3 Multiple key-values for same namespace are separated by a comma "," and multiple namespaces are separated by a semicolon ";". If any of your profile values contains a comma you must not use the namespace abbreviator.

pegasus.catalog.transformation.file

Systems:	Transformation Catalog
Type:	file location string
Default:	\${pegasus.home.sysconfdir}/tc.text \${pegasus.home.sysconfdir}/tc.data
See also:	pegasus.catalog.transformation

This property is used to set the path to the textual transformation catalogs of type File or Text. If the transformation catalog is of type Text then tc.text file is picked up from sysconfdir, else tc.data

Data Staging Configuration

pegasus.data.configuration

System:	Pegasus
Since:	3.1
Type:	enumeration
Value[0]:	sharedfs
Value[1]:	nonsharedfs
Value[2]:	condorio
Default:	sharedfs

This property sets up Pegasus to run in different environments.

sharedfs If this is set, Pegasus will be setup to execute jobs on the shared filesystem on the execution site. This assumes, that the head node of a cluster and the worker nodes share a filesystem. The staging site in this case is the same as the execution site. Pegasus adds a create dir job to the executable workflow that creates a workflow specific directory on the shared filesystem. The data transfer jobs in the executable workflow (stage_in_ , stage_inter_ , stage_out_) transfer the data to this directory. The compute jobs in the executable workflow are launched in the directory on the shared filesystem. Internally, if this is set the following properties are set.

```
pegasus.execute.*.filesystem.local false
```

condorio If this is set, Pegasus will be setup to run jobs in a pure condor pool, with the nodes not sharing a filesystem. Data is staged to the compute nodes from the submit host using Condor File IO. The planner is automatically setup to use the submit host (site local) as the staging site. All the auxillary jobs added by the planner to the executable workflow (create dir, data stagein and stage-out, cleanup) jobs refer to the workflow specific directory on the local site. The data transfer jobs in the executable workflow (stage_in_ , stage_inter_ , stage_out_) transfer the data to this directory. When the compute jobs start, the input data for each job is shipped from the workflow specific directory on the submit host to compute/worker node using Condor file IO. The output data for each job is similarly shipped back to the submit host from the compute/worker node. This setup is particularly helpful when running workflows in the cloud environment where setting up a shared filesystem across the VM's may be tricky. On loading this property, internally the following properties are set

```
pegasus.transfer.sls.*.impl Condor
pegasus.execute.*.filesystem.local true
pegasus.gridstart PegasusLite
pegasus.transfer.worker.package true
```

nonsharedfs If this is set, Pegasus will be setup to execute jobs on an execution site without relying on a shared filesystem between the head node and the worker nodes. You can specify staging site (using --staging-site option to pegasus-plan) to indicate the site to use as a central storage location for a workflow. The staging site is independant of the execution sites on which a workflow executes. All the auxillary jobs added by the planner to the executable workflow (create dir, data stagein and stage-out, cleanup) jobs refer to the workflow specific directory on the staging site. The data transfer jobs in the executable workflow (stage_in_ , stage_inter_ , stage_out_) transfer the data to this directory. When the compute jobs start, the input data for each job is shipped from the workflow specific directory on the submit host to compute/worker node using pegasus-transfer. The output data for each job is similarly shipped back to the submit host from the compute/worker node. The protocols supported are at this time SRM, GridFTP, iRods, S3. This setup is particularly helpful when running workflows on OSG where most of the execution sites don't have enough data storage. Only a few sites have large amounts of data storage exposed that can be used to place data during a workflow run. This setup is also helpful when running workflows in the cloud environment where

setting up a shared filesystem across the VM's may be tricky. On loading this property, internally the following properties are set

```
pegasus.execute.*.filesystem.local    true
pegasus.gridstart                     PegasusLite
pegasus.transfer.worker.package       true
```

Chapter 6. Execution Environments

Pegasus supports a number of execution environments. An execution environment is a setup where jobs from a workflow are running.

Localhost

In this configuration, Pegasus schedules the jobs to run locally on the submit host. Running locally is a good approach for smaller workflows, testing workflows, and for demonstrations such as the Pegasus tutorial. Pegasus supports two methods of local execution: local Condor pool, and shell planner. The former is preferred as the latter does not support all Pegasus' features (such as notifications).

Running on a local Condor pool is achieved by executing the workflow on site local (**--sites local** option to `pegasus-plan`). The site "local" is a reserved site in Pegasus and results in the jobs to run on the submit host in condor universe local. The site catalog can be left very simple in this case:

```
<?xml version="1.0" encoding="UTF-8"?>
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
  schema/sc-4.0.xsd"
  version="4.0">

  <site handle="local" arch="x86_64" os="LINUX">
    <directory type="shared-scratch" path="/tmp/wf/work">
      <file-server operation="all" url="file:///tmp/wf/work"/>
    </directory>
    <directory type="local-storage" path="/tmp/wf/storage">
      <file-server operation="all" url="file:///tmp/wf/storage"/>
    </directory>
  </site>

</sitecatalog>
```

The simplest execution environment does not involve Condor. Pegasus is capable of planning small workflows for local execution using a shell planner. Please refer to the `share/pegasus/examples` directory in your Pegasus installation, the shell planner's documentation section, or the tutorials, for details.

Condor Pool

A Condor pool is a set of machines that use Condor for resource management. A Condor pool can be a cluster of dedicated machines or a set of distributively owned machines. Pegasus can generate concrete workflows that can be executed on a Condor pool.

Figure 6.1. The distributed resources appear to be part of a Condor pool.

The workflow is submitted using DAGMan from one of the job submission machines in the Condor pool. It is the responsibility of the Central Manager of the pool to match the task in the workflow submitted by DAGMan to the execution machines in the pool. This matching process can be guided by including Condor specific attributes in the submit files of the tasks. If the user wants to execute the workflow on the execution machines (worker nodes) in a Condor pool, there should be a resource defined in the site catalog which represents these execution machines. The universe attribute of the resource should be vanilla. There can be multiple resources associated with a single Condor pool, where each resource identifies a subset of machine (worker nodes) in the pool.

When running on a Condor pool, the user has to decide how Pegasus should transfer data. Please see the Data Staging Configuration for the options. The easiest is to use **condorio** as that mode does not require any extra setup - Condor will do the transfers using the existing Condor daemons. For an example of this mode see the example workflow in `share/pegasus/examples/condor-blackdiamond-condorio/`. In condorio mode, the site catalog for the execution site is very simple as storage is provided by Condor:

```

<?xml version="1.0" encoding="UTF-8"?>
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
  schema/sc-4.0.xsd"
  version="4.0">

  <site handle="local" arch="x86_64" os="LINUX">
    <directory type="shared-scratch" path="/tmp/wf/work">
      <file-server operation="all" url="file:///tmp/wf/work"/>
    </directory>
    <directory type="local-storage" path="/tmp/wf/storage">
      <file-server operation="all" url="file:///tmp/wf/storage"/>
    </directory>
  </site>

  <site handle="condorpool" arch="x86_64" os="LINUX">
    <profile namespace="pegasus" key="style" >condor</profile>
    <profile namespace="condor" key="universe" >vanilla</profile>
  </site>

</sitecatalog>
  
```

There is a set of Condor profiles which are used commonly when running Pegasus workflows. You may have to set some or all of these depending on the setup of the Condor pool:

```
<!-- Change the style to Condor for jobs to be executed in the Condor Pool.
      By default, Pegasus creates jobs suitable for grid execution. -->
<profile namespace="pegasus" key="style">condor</profile>

<!-- Change the universe to vanilla to make the jobs go to remote compute
      nodes. The default is local which will only run jobs on the submit host -->
<profile namespace="condor" key="universe" >vanilla</profile>

<!-- The requirements expression allows you to limit where your jobs go -->
<profile namespace="condor" key="requirements">(Target.FileSystemDomain !=
&quot;ygdrasil.isi.edu&quot;)</profile>

<!-- The following two profiles forces Condor to always transfer files. This
      has to be used if the pool does not have a shared filesystem -->
<profile namespace="condor" key="should_transfer_files">True</profile>
<profile namespace="condor" key="when_to_transfer_output">ON_EXIT</profile>
```

Glideins

In this section we describe how machines from different administrative domains and supercomputing centers can be dynamically added to a Condor pool for certain timeframe. These machines join the Condor pool temporarily and can be used to execute jobs in a non preemptive manner. This functionality is achieved using a Condor feature called **glideins** (see <http://cs.wisc.edu/condor/glidein>). The startd daemon is the Condor daemon which provides the compute slots and runs the jobs. In the glidein case, the submit machine is usually a static machine and the glideins are told configured to report to that submit machine. The glideins can be submitted to any type of resource: a GRAM enabled cluster, a campus cluster, a cloud environment such as Amazon AWS, or even another Condor cluster.

Tip

As glideins are usually coming from different compute resource, and/or the glideins are running in an administrative domain different from the submit node, there is usually no shared filesystem available. Thus the most common data staging modes are **condorio** and **nonsharedfs**.

There are many useful tools which submits and manages glideins for you:

- GlideinWMS [<http://www.uscms.org/SoftwareComputing/Grid/WMS/glideinWMS/>] is a tool and host environment used mostly on the Open Science Grid [<http://www.opensciencegrid.org/>].
- CorralWMS [<http://pegasus.isi.edu/projects/corralwms>] is a personal frontend for GlideinWMS. CorralWMS was developed by the Pegasus team and works very well for high throughput workflows.
- condor_glidein [http://research.cs.wisc.edu/condor/manual/v7.6/condor_glidein.html] is a simple glidein tool for Globus GRAM clusters. condor_glidein is shipped with Condor.
- Glideins can also be created by hand or scripts. This is a useful solution for example for cluster which have no external job submit mechanisms or do not allow outside networking.

CondorC

Using CondorC users can submit workflows to remote condor pools. CondorC is a condor specific solution for remote submission that does not involve the setting up a GRAM on the headnode. To enable CondorC submission to a site, user needs to associate pegasus profile key named style with value as condorc. In case, the remote Condor pool does not have a shared filesystem between the nodes making up the pool, users should use pegasus in the condorio data configuration. In this mode, all the data is staged to the remote node in the Condor pool using Condor File transfers and is executed using PegasusLite.

A sample site catalog for submission to a CondorC enabled site is listed below

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
```

```

        version="4.0">

<site handle="local" arch="x86_64" os="LINUX">
  <directory type="shared-scratch" path="/tmp/wf/work">
    <file-server operation="all" url="file:///tmp/wf/work"/>
  </directory>
  <directory type="local-storage" path="/tmp/wf/storage">
    <file-server operation="all" url="file:///tmp/wf/storage"/>
  </directory>
</site>

<site handle="condorcpool" arch="x86_86" os="LINUX">
  <!-- the grid gateway entries are used to designate
        the remote schedd for the CondorC pool -->
  <grid type="condor" contact="ccg-condorctest.isi.edu" scheduler="Condor"
jobtype="compute" />
  <grid type="condor" contact="ccg-condorctest.isi.edu" scheduler="Condor"
jobtype="auxillary" />

  <!-- enable submission using condorc -->
  <profile namespace="pegasus" key="style">condorc</profile>

  <!-- specify which condor collector to use.
        If not specified defaults to remote schedd specified in grid gateway -->
  <profile namespace="condor" key="condor_collector">condorc-collector.isi.edu</profile>

  <profile namespace="condor" key="should_transfer_files">Yes</profile>
  <profile namespace="condor" key="when_to_transfer_output">ON_EXIT</profile>
  <profile namespace="env" key="PEGASUS_HOME" >/usr</profile>
  <profile namespace="condor" key="universe">vanilla</profile>

</site>

</sitecatalog>

```

To enable PegasusLite in CondorIO mode, users should set the following in their properties

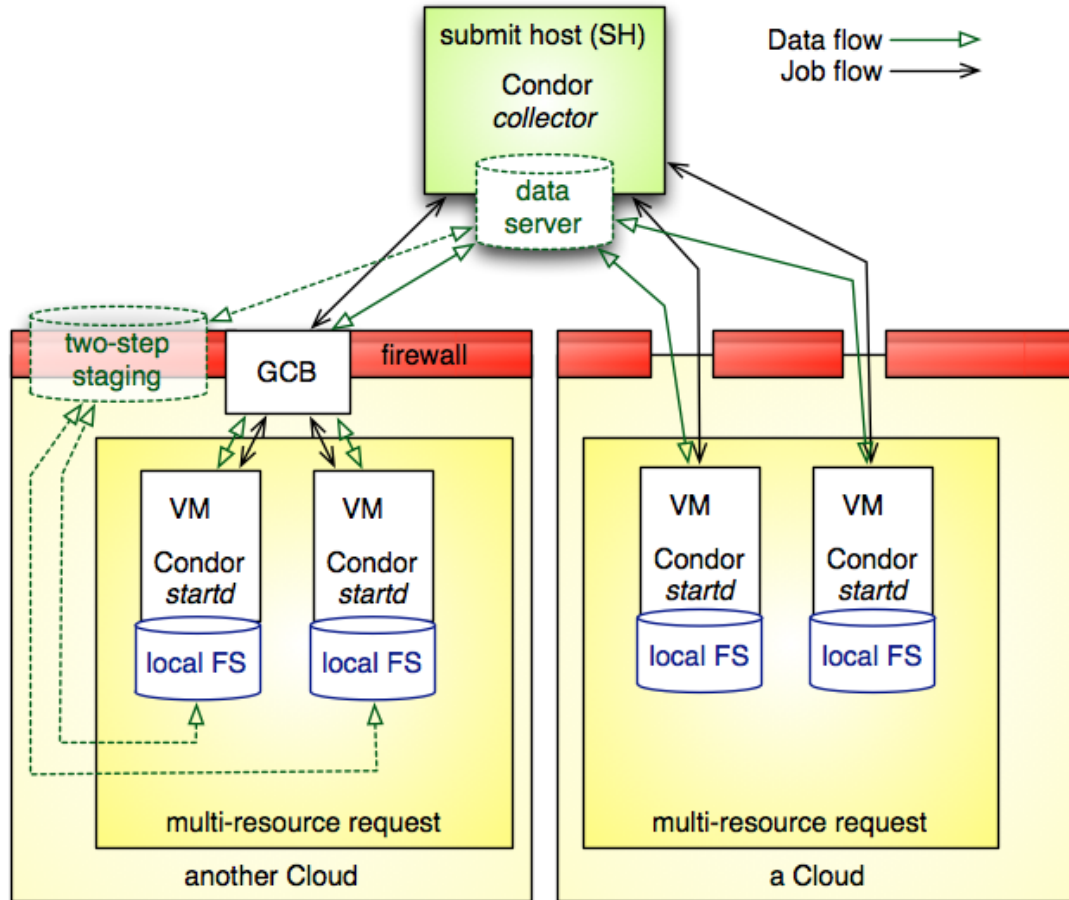

```

# pegasus properties
pegasus.data.configuration    condorio

```

Infrastructure Clouds

Figure 6.2. Cloud Sample Site Layout

This figure shows a sample environment for executing Pegasus on multiple clouds (known as "sky computing"). At this point, it is up to the user to provision the remote resources with a proper VM image that includes a Condor worker that is configured to report back to a Condor master outside the cloud.

In this discussion, the *submit host* (SH) is located logically external to the cloud provider(s). The SH is the point where a user submits Pegasus workflows for execution. This site typically runs a Condor collector to gather resource announcements, or is part of a larger Condor pool that collects these announcements. Condor makes the remote resources available to the submit host's Condor installation.

The figure above shows the way Pegasus WMS is deployed in cloud computing resources, ignoring how these resources were provisioned. The provisioning request shows multiple resources per provisioning request.

The provisioning broker -- Nimbus, Eucalyptus or EC2 -- at the remote site is responsible to allocate and set up the resources. For a multi-node request, the worker nodes often require access to a form of shared data storage. Concretely, either a POSIX-compliant shared file system (e.g. NFS, PVFS) is available to the nodes, or can be brought up for the lifetime of the application workflow. The task steps of the application workflow facilitate shared file systems to exchange intermediary results between tasks on the same cloud site. Pegasus also supports an S3 data mode for the application workflow data staging.

The initial stage-in and final stage-out of application data into and out of the node set is part of any Pegasus-planned workflow. Several configuration options exist in Pegasus to deal with the dynamics of push and pull of data, and when to stage data. In many use-cases, some form of external access to or from the shared file system that is visible to the

application workflow is required to facilitate successful data staging. However, Pegasus is prepared to deal with a set of boundary cases.

The data server in the figure is shown at the submit host. This is not a strict requirement. The data server for consumed data and data products may both be different and external to the submit host.

Once resources begin appearing in the pool managed by the submit machine's Condor collector, the application workflow can be submitted to Condor. A Condor DAGMan will manage the application workflow execution. Pegasus run-time tools obtain timing-, performance and provenance information as the application workflow is executed. At this point, it is the user's responsibility to de-provision the allocated resources.

In the figure, the cloud resources on the right side are assumed to have uninhibited outside connectivity. This enables the Condor I/O to communicate with the resources. The right side includes a setup where the worker nodes use all private IP, but have out-going connectivity and a NAT router to talk to the internet. The *Condor connection broker* (CCB) facilitates this setup almost effortlessly.

The left side shows a more difficult setup where the connectivity is fully firewalled without any connectivity except to in-site nodes. In this case, a proxy server process, the *generic connection broker* (GCB), needs to be set up in the DMZ of the cloud site to facilitate Condor I/O between the submit host and worker nodes.

If the cloud supports data storage servers, Pegasus is starting to support workflows that require staging in two steps: Consumed data is first staged to a data server in the remote site's DMZ, and then a second staging task moves the data from the data server to the worker node where the job runs. For staging out, data needs to be first staged from the job's worker node to the site's data server, and possibly from there to another data server external to the site. Pegasus is capable to plan both steps: Normal staging to the site's data server, and the worker-node staging from and to the site's data server as part of the job.

Amazon EC2

There are many different ways to set up an execution environment in Amazon EC2. The easiest way is to use a submit machine outside the cloud, and to provision several worker nodes and a file server node in the cloud as shown here:

Figure 6.3. Amazon EC2

The submit machine runs Pegasus and a Condor master (collector, schedd, negotiator). The workers run a Condor startd. And the file server node exports an NFS file system. The startd on the workers is configured to connect to the master running outside the cloud, and the workers also mount the NFS file system. More information on setting up Condor for this environment can be found at <http://www.isi.edu/~gideon/condor-ec2> [<http://www.isi.edu/~gideon/condor-ec2/>].

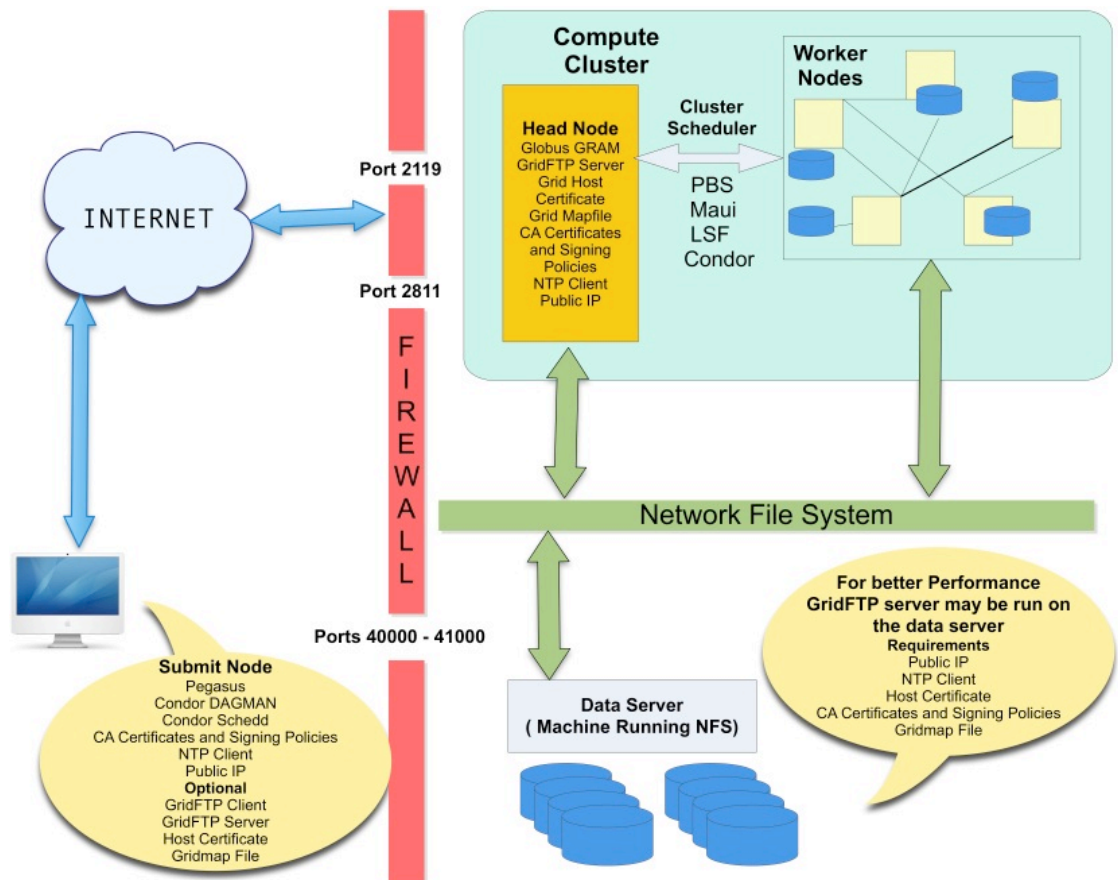

The site catalog entry for this configuration is similar to what you would create for running on a local Condor pool with a shared file system.

FutureGrid

FutureGrid [<https://portal.futuregrid.org/>] is a distributed testbed for cloud computing. There is a tutorial on how to run Pegasus on FutureGrid using the Nimbus cloud management system here: <http://pegasus.isi.edu/futuregrid/tutorials> [<http://pegasus.isi.edu/futuregrid/tutorials/>]

Remote Cluster using Globus GRAM

Figure 6.4. Grid Sample Site Layout

A generic grid environment shown in the figure above. We will work from the left to the right top, then the right bottom.

On the left side, you have a submit machine where Pegasus runs, Condor schedules jobs, and workflows are executed. We call it the *submit host* (SH), though its functionality can be assumed by a virtual machine image. In order to properly communicate over secured channels, it is important that the submit machine has a proper notion of time, i.e. runs an NTP daemon to keep accurate time. To be able to connect to remote clusters and receive connections from the remote clusters, the submit host has a public IP address to facilitate this communication.

In order to send a job request to the remote cluster, Condor wraps the job into Globus calls via Condor-G. Globus uses GRAM to manage jobs on remote sites. In terms of a software stack, Pegasus wraps the job into Condor. Condor wraps the job into Globus. Globus transports the job to the remote site, and unwraps the Globus component, sending it to the remote site's *resource manager* (RM).

To be able to communicate using the Globus security infrastructure (GSI), the submit machine needs to have the certificate authority (CA) certificates configured, requires a host certificate in certain circumstances, and the user a

user certificate that is enabled on the remote site. On the remote end, the remote gatekeeper node requires a host certificate, all signing CA certificate chains and policy files, and a good time source.

In a grid environment, there are one or more clusters accessible via grid middleware like the Globus Toolkit [http://www.globus.org/]. In case of Globus, there is the Globus gatekeeper listening on TCP port 2119 of the remote cluster. The port is opened to a single machine called *head node* (HN). The head-node is typically located in a de-militarized zone (DMZ) of the firewall setup, as it requires limited outside connectivity and a public IP address so that it can be contacted. Additionally, once the gatekeeper accepted a job, it passes it on to a jobmanager. Often, these jobmanagers require a limited port range, in the example TCP ports 40000-41000, to call back to the submit machine.

For the user to be able to run jobs on the remote site, the user must have some form of an account on the remote site. The user's grid identity is passed from the submit host. An entity called *grid mapfile* on the gatekeeper maps the user's grid identity into a remote account. While most sites do not permit account sharing, it is possible to map multiple user certificates to the same account.

The gatekeeper is the interface through which jobs are submitted to the remote cluster's resource manager. A resource manager is a scheduling system like PBS, Maui, LSF, FBSNG or Condor that queues tasks and allocates worker nodes. The *worker nodes* (WN) in the remote cluster might not have outside connectivity and often use all private IP addresses. The Globus toolkit requires a shared filesystem to properly stage files between the head node and worker nodes.

Note

The shared filesystem requirement is imposed by Globus. Pegasus is capable of supporting advanced site layouts that do not require a shared filesystem. Please contact us for details, should you require such a setup.

To stage data between external sites for the job, it is recommended to enable a GridFTP server. If a shared networked filesystem is involved, the GridFTP server should be located as close to the file-server as possible. The GridFTP server requires TCP port 2811 for the control channel, and a limited port range for data channels, here as an example the TCP ports from 40000 to 41000. The GridFTP server requires a host certificate, the signing CA chain and policy files, a stable time source, and a gridmap file that maps between a user's grid identity and the user's account on the remote site.

The GridFTP server is often installed on the head node, the same as the gatekeeper, so that they can share the grid mapfile, CA certificate chains and other setups. However, for performance purposes it is recommended that the GridFTP server has its own machine.

An example site catalog entry for a GRAM enabled site looks as follow in the site catalog

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
  version="4.0">

  <site handle="Trestles" arch="x86_64" os="LINUX">
    <grid type="gt5" contact="trestles.sdsc.edu/jobmanager-fork" scheduler="Fork"
    jobtype="auxillary"/>
    <grid type="gt5" contact="trestles.sdsc.edu/jobmanager-pbs" scheduler="unknown"
    jobtype="compute"/>

    <directory type="shared-scratch" path="/oasis/projects/nsf/USERNAME">
      <file-server operation="all" url="gsiftp://trestles-dml.sdsc.edu/oasis/projects/nsf/
USERNAME"/>
    </directory>

    <!-- specify the path to a PEGASUS WORKER INSTALL on the site -->
    <profile namespace="env" key="PEGASUS_HOME" >/path/to/PEGASUS/INSTALL</profile>
  </site>

</sitecatalog>
```

Remote Cluster using CREAMCE

CREAM [https://wiki.italiangrid.it/twiki/bin/view/CREAM/FunctionalDescription] is a webservices based job submission front end for remote compute clusters. It can be viewed as a replacement for Globus GRAM and is mainly popular in Europe. It is widely used in the Italian Grid.

In order to submit a workflow to compute site using the CREAMCE front end, the user needs to specify the following for the site in their site catalog

1. **pegasus** profile **style** with value set to **cream**
2. **grid** gateway defined for the site with **contact** attribute set to CREAMCE frontend and **scheduler** attribute to remote scheduler.
3. a remote queue can be optionally specified using **globus** profile **queue** with value set to **queue-name**

An example site catalog entry for a creamce site looks as follow in the site catalog

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
  version="4.0">

  <site handle="creamce" arch="x86" os="LINUX">
    <grid type="cream" contact="https://ce01-lcg.cr.cnaf.infn.it:8443/ce-cream/services/CREAM2"
    scheduler="LSF" jobtype="compute" />
    <grid type="cream" contact="https://ce01-lcg.cr.cnaf.infn.it:8443/ce-cream/services/CREAM2"
    scheduler="LSF" jobtype="auxillary" />

    <directory type="shared-scratch" path="/home/virgo034">
      <file-server operation="all" url="gsiftp://ce01-lcg.cr.cnaf.infn.it/home/virgo034"/>
    </directory>

    <profile namespace="pegasus" key="style">cream</profile>
    <profile namespace="globus" key="queue">virgo</profile>
  </site>

</sitecatalog>
```

The pegasus distribution comes with creamce examples in the examples directory. They can be used as a starting point to configure your setup.

Tip

Usually , the CREAMCE frontends accept VOMS generated user proxies using the command voms-proxy-init . Steps on generating a VOMS proxy are listed in the CREAM User Guide here [https://wiki.italiangrid.it/wiki/bin/view/CREAM/UserGuide#1_1_Before_starting_get_your_use] .

Local Cluster Using Glite

This section describes the various changes required in the site catalog for Pegasus to generate an executable workflow that uses gLite blahp to directly submit to PBS on the local machine. This mode of submission should only be used when the condor on the submit host can directly talk to scheduler running on the cluster. It is recommended that the cluster that gLite talks to is designated as a separate compute site in the Pegasus site catalog. To tag a site as a gLite site the following two profiles need to be specified for the site in the site catalog

1. **pegasus** profile **style** with value set to **glite**.
2. **condor** profile **grid_resource** with value set to **pbs|lsf**

An example site catalog entry for a glite site looks as follows in the site catalog

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
  version="4.0">

  <site handle="local" arch="x86" os="LINUX">
    <directory type="shared-scratch" path="/lfs/shared-scratch/glite-sharedfs-example/work">
```

```
        <file-server operation="all" url="file:///lfs/local-scratch/glite-sharedfs-example/
work" />
      </directory>
      <directory type="local-storage" path="/shared-scratch//glite-sharedfs-example/outputs">
        <file-server operation="all" url="file:///lfs/local-scratch/glite-sharedfs-example/
outputs" />
      </directory>
    </site>

    <site handle="local-pbs" arch="x86" os="LINUX">

      <!-- the following is a shared directory shared amongst all the nodes in the cluster -->
      <directory type="shared-scratch" path="/lfs/glite-sharedfs-example/local-pbs/shared-
scratch">
        <file-server operation="all" url="file:///lfs/glite-sharedfs-example/local-pbs/shared-
scratch" />
      </directory>

      <profile namespace="env" key="PEGASUS_HOME">/lfs/software/pegasus/pegasus-4.2.0</profile>

      <profile namespace="pegasus" key="style" >glite</profile>
      <profile namespace="pegasus" key="change.dir">true</profile>

      <profile namespace="condor" key="grid_resource">pbs</profile>
      <profile namespace="condor" key="batch_queue">batch</profile>
      <profile namespace="globus" key="maxwalltime">30000</profile>
    </site>

</sitecatalog>
```

Tip

Starting 4.2.1 , in the examples directory you can find a glite shared filesystem example that you can use to test out this configuration

Changes to Jobs

As part of applying the style to the job, this style adds the following classads expressions to the job description.

1. +remote_queue - value picked up from globus profile queue
2. +remote_cerequirements - See below

Remote CE Requirements

The remote CE requirements are constructed from the following profiles associated with the job. The profiles for a job are derived from various sources

1. transformation catalog
2. site catalog
3. DAX
4. user properties

The following globus profiles if associated with the job are picked up and translated to corresponding glite key

1. hostcount -> PROCS
2. count -> NODES
3. maxwalltime -> WALLTIME

The following condor profiles if associated with the job are picked up and translated to corresponding glite key

1. priority -> PRIORITY

All the env profiles are translated to MYENV

The remote_cerequirements expression is constructed on the basis of the profiles associated with job . An example +remote_cerequirements classad expression in the submit file is listed below

```
+remote_cerequirements = "PROCS==18 && NODES==1 && PRIORITY==10 && WALLTIME==3600 \
&& PASSENV==1 && JOBNAME=="TEST JOB" && MYENV ==\"JAVA_HOME=/bin/java,APP_HOME=/bin/app\""
```

Specifying directory for the jobs

gLite blahp does not follow the remote_initialdir or initialdir classad directives. Hence, all the jobs that have this style applied don't have a remote directory specified in the submit directory. Instead, Pegasus relies on kickstart to change to the working directory when the job is launched on the remote node.

Remote Cluster using BOSCO and SSH submissions

BOSCO [<http://bosco.opensciencegrid.org/about/>] enables users to submit jobs to remote clusters using SSH. This section describes how to specify a site catalog entry for a site to which jobs can be submitted over SSH. To tag a site for SSH submission, the following profiles need to be specified for the site in the site catalog:

1. **pegasus** profile **style** with value set to **ssh**
2. Specify the service information as grid gateways. This should match what Bosco provided when the cluster was set up.

An example site catalog entry for a BOSCO site looks as follows in the site catalog

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
  version="4.0">

  <site handle="USC_HPCC_Bosco" arch="x86_64" os="LINUX">

    <!-- Specify the service information as grid gateways. This should match what Bosco provided
when the cluster
was set up. -->
    <grid type="batch" contact="username@hpc-login2.usc.edu" scheduler="PBS" jobtype="compute"/>
    <grid type="batch" contact="username@hpc-login2.usc.edu" scheduler="PBS"
jobtype="auxillary"/>

    <!-- Scratch directory on the cluster -->
    <directory type="shared-scratch" path="/home/rcf-40/tmp">
      <file-server operation="all" url="scp://username@hpc-login2.usc.edu/home/rcf-40/tmp"/>
    </directory>

    <!-- SSH is the style to use for Bosco SSH submits -->
    <profile namespace="pegasus" key="style">ssh</profile>

    <!-- Bosco is using the grid universe, which means the globus
namespace can be used to control the jobs -->
    <profile namespace="globus" key="queue">default</profile>
    <profile namespace="globus" key="maxwalltime">30</profile>

  </site>

</sitecatalog>
```

Note

It is recommended to have a submit node configured either as a BOSCO submit node or a vanilla HTCondor node. You cannot have HTCondor configured both as a BOSCO install and a traditional HTCondor submit node at the same time as BOSCO will override the traditional HTCondor pool in the user environment.

Starting 4.3 there is a bosco-shared-fs example in the examples directory of the distribution.

Campus Cluster

There are almost as many different configurations of campus clusters as there are campus clusters, and because of that it can be hard to determine what the best way to run Pegasus workflows. Below is a ordered checklist with some ideas we have collected from working with users in the past:

1. If the cluster scheduler is Condor, please see the Condor Pool section.
2. If the cluster is Globus GRAM enabled, see the Globus GRAM section. If you have have a lot of short jobs, also read the Glidein section.
3. For clusters without GRAM, you might be able to do glideins. If outbound network connectivity is allowed, your submit host can be anywhere. If the cluster is setup to not allow any network connections to the outside, you will probably have to run the submit host inside the cluster as well.

If the cluster you are trying to use is not fitting any of the above scenarios, please post to the Pegasus users mailing list [<http://pegasus.isi.edu/support>] and we will help you find a solution.

XSEDE

The Extreme Science and Engineering Discovery Environment (XSEDE) [<https://www.xsede.org/>] provides a set of High Performance Computing (HPC) and High Throughput Computing (HTC) resources.

For the HPC resources, it is recommended to run using Globus GRAM or glideins. Most of these resources have fast parallel file systems, so running with sharedfs data staging is recommended. Below is example site catalog and pegasusrc to run on SDSC Trestles [<http://www.sdsc.edu/us/resources/trestles/>]:

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog http://pegasus.isi.edu/
schema/sc-4.0.xsd"
  version="4.0">

  <site handle="local" arch="x86_64" os="LINUX">
    <directory type="shared-scratch" path="/tmp/wf/work">
      <file-server operation="all" url="file:///tmp/wf/work"/>
    </directory>
    <directory type="local-storage" path="/tmp/wf/storage">
      <file-server operation="all" url="file:///tmp/wf/storage"/>
    </directory>
  </site>

  <site handle="Trestles" arch="x86_64" os="LINUX">
    <grid type="gt5" contact="trestles.sdsc.edu:2119/jobmanager-fork" scheduler="PBS"
jobtype="auxillary"/>
    <grid type="gt5" contact="trestles.sdsc.edu:2119/jobmanager-pbs" scheduler="PBS"
jobtype="compute"/>
    <directory type="shared-scratch" path="/phase1/USERNAME">
      <file-server operation="all" url="gsiftp://trestles-dml.sdsc.edu/phase1/USERNAME"/>
    </directory>
  </site>

</sitecatalog>
```

pegasusrc:

```
pegasus.catalog.replica=SimpleFile
pegasus.catalog.replica.file=rc

pegasus.catalog.site.file=sites.xml

pegasus.catalog.transformation=Text
pegasus.catalog.transformation.file=tc

pegasus.data.configuration = sharedfs
```

```
# Pegasus might not be installed, or be of a different version
# so stage the worker package
pegasus.transfer.worker.package = true
```

The HTC resources available on XSEDE are all Condor based, so standard Condor Pool setup will work fine.

If you need to run high throughput workloads on the HPC machines (for example, post processing after a large parallel job), glideins can be useful as it is a more efficient method for small jobs on these systems.

Open Science Grid Using glideinWMS

glideinWMS [<http://www.uscms.org/SoftwareComputing/Grid/WMS/glideinWMS/>] is a glidein system widely used on Open Science Grid. Running on top of glideinWMS is like running on a Condor Pool without a shared filesystem.

Chapter 7. Submit Directory Details

This chapter describes the submit directory content after Pegasus has planned a workflow. Pegasus takes in an abstract workflow (DAX) and generates an executable workflow (DAG) in the submit directory.

This document also describes the various Replica Selection Strategies in Pegasus.

Layout

Each executable workflow is associated with a submit directory, and includes the following:

1. **<daxlabel-daxindex>.dag**

This is the Condor DAGMan dag file corresponding to the executable workflow generated by Pegasus. The dag file describes the edges in the DAG and information about the jobs in the DAG. Pegasus generated .dag file usually contains the following information for each job

- a. The job submit file for each job in the DAG.
- b. The post script that is to be invoked when a job completes. This is usually located at **\$PEGASUS_HOME/bin/exitpost** and parses the kickstart record in the job's **.out file** and determines the exitcode.
- c. **JOB RETRY** - the number of times the job is to be retried in case of failure. In Pegasus, the job postscript exits with a non zero exitcode if it determines a failure occurred.

2. **<daxlabel-daxindex>.dag.dagman.out**

When a DAG (.dag file) is executed by Condor DAGMan , the DAGMan writes out it's output to the **<daxlabel-daxindex>.dag.dagman.out file** . This file tells us the progress of the workflow, and can be used to determine the status of the workflow. Most of pegasus tools mine the **dagman.out** or **jobstate.log** to determine the progress of the workflows.

3. **<daxlabel-daxindex>.static.bp**

This file contains netlogger events that link jobs in the DAG with the jobs in the DAX. This file is parsed by pegasus-monitor when a workflow starts and populated to the stampede backend.

4. **<daxlabel-daxindex>.notify**

This file contains all the notifications that need to be set for the workflow and the jobs in the executable workflow. The format of notify file is described here

5. **<daxlabel-daxindex>.replica.store**

This is a file based replica catalog, that only lists file locations are mentioned in the DAX.

6. **<daxlabel-daxindex>.dot**

Pegasus creates a dot file for the executable workflow in addition to the .dag file. This can be used to visualize the executable workflow using the dot program.

7. **<job>.sub**

Each job in the executable workflow is associated with it's own submit file. The submit file tells Condor how to execute the job.

8. **<job>.out.00n**

The stdout of the executable referred in the job submit file. In Pegasus, most jobs are launched via kickstart. Hence, this file contains the kickstart XML provenance record that captures runtime provenance on the remote node where the job was executed. n varies from 1-N where N is the **JOB RETRY** value in the .dag file. The exitpost executable

is invoked on the <job>.out file and it moves the <job>.out to <job>.out.00n so that the the job's .out files are preserved across retries.

9. <job>.err.00n

The stderr of the executable referred in the job submit file. In case of Pegasus, mostly the jobs are launched via kickstart. Hence, this file contains stderr of kickstart. This is usually empty unless there is an error in kickstart e.g. kickstart segfaults, or kickstart location specified in the submit file is incorrect. The exitpost executable is invoked on the <job>.out file and it moves the <job>.err to <job>.err.00n so that the the job's .out files are preserved across retries.

10.jobstate.log

The jobstate.log file is written out by the pegasus-monitord daemon that is launched when a workflow is submitted for execution by pegasus-run. The pegasus-monitord daemon parses the dagman.out file and writes out the jobstate.log that is easier to parse. The jobstate.log captures the various states through which a job goes during the workflow. There are other monitoring related files that are explained in the monitoring chapter.

11.braindump.txt

Contains information about pegasus version, dax file, dag file, dax label.

Condor DAGMan File

The Condor DAGMan file (.dag) is the input to Condor DAGMan (the workflow executor used by Pegasus) .

Pegasus generated .dag file usually contains the following information for each job:

1. The job submit file for each job in the DAG.
2. The post script that is to be invoked when a job completes. This is usually found in **\$PEGASUS_HOME/bin/exitpost** and parses the kickstart record in the job's .out file and determines the exitcode.
3. JOB RETRY - the number of times the job is to be retried in case of failure. In case of Pegasus, job postscript exits with a non zero exitcode if it determines a failure occurred.
4. The pre script to be invoked before running a job. This is usually for the dax jobs in the DAX. The pre script is pegasus-plan invocation for the subdax.

In the last section of the DAG file the relations between the jobs (that identify the underlying DAG structure) are highlighted.

Sample Condor DAG File

```

Kickstart XML Record

Kickstart is a light weight C executable that is shipped with the pegasus worker package. All jobs are launched via Kickstart on the remote end, unless explicitly disabled at the time of running pegasus-plan.

Kickstart does not work with:

1. Condor Standard Universe Jobs
2. MPI Jobs

Pegasus automatically disables kickstart for the above jobs.

Kickstart captures useful runtime provenance information about the job launched by it on the remote node, and puts in an XML record that it writes to its own stdout. The stdout appears in the workflow submit directory as <job>.out.00n. The following information is captured by kickstart and logged:

1. The exitcode with which the job it launched exited.
2. The duration of the job
3. The start time for the job
4. The node on which the job ran

5. The stdout and stderr of the job
6. The arguments with which it launched the job
7. The environment that was set for the job before it was launched.
8. The machine information about the node that the job ran on

Amongst the above information, the dagman.out file gives a coarser grained estimate of the job duration and start time.

Reading a Kickstart Output File

The kickstart file below has the following fields highlighted:

1. The host on which the job executed and the ipaddress of that host
2. The duration and start time of the job. The time here is in reference to the clock on the remote node where the job is executed.
3. The exitcode with which the job executed
4. The arguments with which the job was launched.
5. The directory in which the job executed on the remote site
6. The stdout of the job
7. The stderr of the job
8. The environment of the job

Jobstate.Log File

The jobstate.log file logs the various states that a job goes through during workflow execution. It is created by the **pegasus-monitord** daemon that is launched when a workflow is submitted to Condor DAGMan by pegasus-run.

pegasus-monitord parses the dagman.out file and writes out the jobstate.log file, the format of which is more amenable to parsing.

Note

The jobstate.log file is not created if a user uses condor_submit_dag to submit a workflow to Condor DAG-Man.

The jobstate.log file can be created after a workflow has finished executing by running **pegasus-monitord** on the .dagman.out file in the workflow submit directory.

Below is a snippet from the jobstate.log for a single job executed via condorg:

```
1239666049 create_dir_blackdiamond_0_isi_viz SUBMIT 3758.0 isi_viz - 1
1239666059 create_dir_blackdiamond_0_isi_viz EXECUTE 3758.0 isi_viz - 1
1239666059 create_dir_blackdiamond_0_isi_viz GLOBUS_SUBMIT 3758.0 isi_viz - 1
1239666059 create_dir_blackdiamond_0_isi_viz GRID_SUBMIT 3758.0 isi_viz - 1
1239666064 create_dir_blackdiamond_0_isi_viz JOB_TERMINATED 3758.0 isi_viz - 1
1239666064 create_dir_blackdiamond_0_isi_viz JOB_SUCCESS 0 isi_viz - 1
1239666064 create_dir_blackdiamond_0_isi_viz POST_SCRIPT_STARTED - isi_viz - 1
1239666069 create_dir_blackdiamond_0_isi_viz POST_SCRIPT_TERMINATED 3758.0 isi_viz - 1
1239666069 create_dir_blackdiamond_0_isi_viz POST_SCRIPT_SUCCESS - isi_viz - 1
```

Each entry in jobstate.log has the following:

1. The ISO timestamp for the time at which the particular event happened.
2. The name of the job.
3. The event recorded by DAGMan for the job.
4. The condor id of the job in the queue on the submit node.
5. The pegasus site to which the job is mapped.
6. The job time requirements from the submit file.
7. The job submit sequence for this workflow.

Table 7.1. Table 1: The job lifecycle when executed as part of the workflow

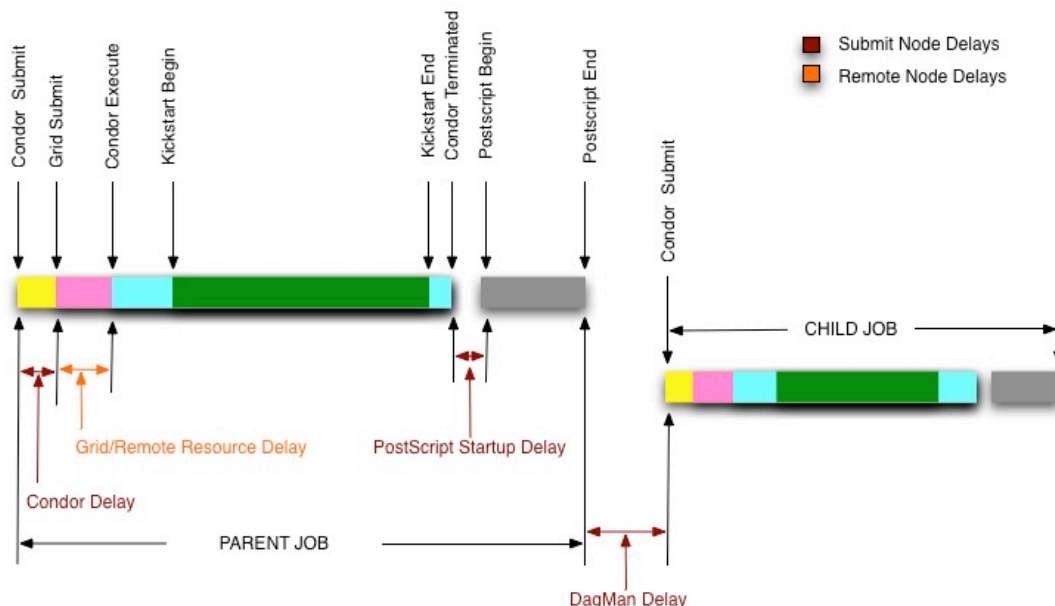

STATE/EVENT	DESCRIPTION
SUBMIT	job is submitted by condor schedd for execution.
EXECUTE	condor schedd detects that a job has started execution.
GLOBUS_SUBMIT	the job has been submitted to the remote resource. It's only written for GRAM jobs (i.e. gt2 and gt4).
GRID_SUBMIT	same as GLOBUS_SUBMIT event. The ULOG_GRID_SUBMIT event is written for all grid universe jobs./
JOB_TERMINATED	job terminated on the remote node.
JOB_SUCCESS	job succeeded on the remote host, condor id will be zero (successful exit code).
JOB_FAILURE	job failed on the remote host, condor id will be the job's exit code.
POST_SCRIPT_STARTED	post script started by DAGMan on the submit host, usually to parse the kickstart output
POST_SCRIPT_TERMINATED	post script finished on the submit node.
POST_SCRIPT_SUCCESS POST_SCRIPT_FAILURE	post script succeeded or failed.

There are other monitoring related files that are explained in the monitoring chapter.

Pegasus Workflow Job States and Delays

The various job states that a job goes through (as captured in the dagman.out and jobstate.log file) during it's lifecycle are illustrated below. The figure below highlights the various local and remote delays during job lifecycle.

PEGASUS WORKFLOW JOB STATES AND DELAYS

Braindump File

The braindump file is created per workflow in the submit file and contains metadata about the workflow.

Table 7.2. Table 2: Information Captured in Braindump File

KEY	DESCRIPTION
user	the username of the user that ran pegasus-plan
grid_dn	the Distinguished Name in the proxy
submit_hostname	the hostname of the submit host
root_wf_uuid	the workflow uuid of the root workflow
wf_uuid	the workflow uuid of the current workflow i.e the one whose submit directory the braindump file is.
dax	the path to the dax file
dax_label	the label attribute in the adag element of the dax
dax_index	the index in the dax.
dax_version	the version of the DAX schema that DAX referred to.
pegasus_wf_name	the workflow name constructed by pegasus when planning
timestamp	the timestamp when planning occurred
basedir	the base submit directory
submit_dir	the full path for the submit directory
properties	the full path to the properties file in the submit directory

planner	the planner used to construct the executable workflow. always pegasus
planner_version	the versions of the planner
pegasus_build	the build timestamp
planner_arguments	the arguments with which the planner is invoked.
jsd	the path to the jobstate file
rundir	the rundir in the numbering scheme for the submit directories
pegasushome	the root directory of the pegasus installation
vogroup	the vo group to which the user belongs to. Defaults to pegasus
condor_log	the full path to condor common log in the submit directory
notify	the notify file that contains any notifications that need to be sent for the workflow.
dag	the basename of the dag file created
type	the type of executable workflow. Can be dag shell

A Sample Braindump File is displayed below:

```

user vahi
grid_dn null
submit_hostname obelix
root_wf_uuid a4045eb6-317a-4710-9a73-96a745cb1fe8

vogroup pegasus
condor_log Stampede-Test-0.log
notify Stampede-Test-0.notify
dag Stampede-Test-0.dag
type dag

```

Pegasus static.bp File

Pegasus creates a workflow.static.bp file that links jobs in the DAG with the jobs in the DAX. The contents of the file are in netlogger format. The purpose of this file is to be able to link an invocation record of a task to the corresponding job in the DAX

The workflow is replaced by the name of the workflow i.e. same prefix as the .dag file

In the file there are five types of events:

- task.info

This event is used to capture information about all the tasks in the DAX(abstract workflow)

- task.edge

This event is used to capture information about the edges between the tasks in the DAX (abstract workflow)

- job.info

This event is used to capture information about the jobs in the DAG (executable workflow generated by Pegasus)

- job.edge

This event is used to capture information about edges between the jobs in the DAG (executable workflow).

- wf.map.task_job

This event is used to associate the tasks in the DAX with the corresponding jobs in the DAG.

Chapter 8. Monitoring, Debugging and Statistics

Pegasus comes bundled with useful tools that help users debug workflows and generate useful statistics and plots about their workflow runs. These tools internally parse the Condor log files and have a similar interface. With the exception of `pegasus-monitor` (see below), all tools take in the submit directory as an argument. Users can invoke the tools listed in this chapter as follows:

```
$ pegasus-[toolname] <path to the submit directory>
```

All these utilities query a database (usually a sqlite in the workflow submit directory) that is populated by the monitoring daemon **pegasus-monitor** .

Workflow Status

As the number of jobs and tasks in workflows increase, the ability to track the progress and quickly debug a workflow becomes more and more important. Pegasus comes with a series of utilities that can be used to monitor and debug workflows both in real-time as well as after execution is already completed.

pegasus-status

To monitor the execution of the workflow run the **pegasus-status** command as suggested by the output of the **pegasus-run** command. **pegasus-status** shows the current status of the Condor Q as pertaining to the master workflow from the workflow directory you are pointing it to. In a second section, it will show a summary of the state of all jobs in the workflow and all of its sub-workflows.

The details of **pegasus-status** are described in its respective manual page. There are many options to help you gather the most out of this tool, including a watch-mode to repeatedly draw information, various modes to add more information, and legends if you are new to it, or need to present it.

```
$ pegasus-status /Workflow/dags/directory
STAT IN_STATE JOB
Run    05:08 level-3-0
Run    04:32 |-sleep_ID000005
Run    04:27 \_subdax_level-2_ID000004
Run    03:51 |-sleep_ID000003
Run    03:46 \_subdax_level-1_ID000002
Run    03:10 \_sleep_ID000001
Summary: 6 Condor jobs total (R:6)

UNREADY  READY  PRE  QUEUED  POST  SUCCESS  FAILURE  %DONE
0         0      0      6      0      3        0    33.3
Summary: 3 DAGs total (Running:3)
```

Without the `-l` option, the only a summary of the workflow statistics is shown under the current queue status. However, with the `-l` option, it will show each sub-workflow separately:

```
$ pegasus-status -l /Workflow/dags/directory
STAT IN_STATE JOB
Run    07:01 level-3-0
Run    06:25 |-sleep_ID000005
Run    06:20 \_subdax_level-2_ID000004
Run    05:44 |-sleep_ID000003
Run    05:39 \_subdax_level-1_ID000002
Run    05:03 \_sleep_ID000001
Summary: 6 Condor jobs total (R:6)

UNRDY  READY  PRE  IN_Q  POST  DONE  FAIL  %DONE  STATE  DAGNAME
0       0      0    1    0    1    0   50.0  Running  level-2_ID000004/level-1_ID000002/
level-1-0.dag
0       0      0    2    0    1    0   33.3  Running  level-2_ID000004/level-2-0.dag
0       0      0    3    0    1    0   25.0  Running  *level-3-0.dag
0       0      0    6    0    3    0   33.3          TOTALS (9 jobs)
Summary: 3 DAGs total (Running:3)
```

The following output shows a successful workflow of workflow summary after it has finished.

```
$ pegasus-status work/2011080514
(no matching jobs found in Condor Q)
UNREADY  READY    PRE  QUEUED    POST SUCCESS FAILURE %DONE
      0      0      0      0      0    7,137      0 100.0
Summary: 44 DAGs total (Success:44)
```

Warning

For large workflows with many jobs, please note that **pegasus-status** will take time to compile state from all workflow files. This typically affects the initial run, and sub-sequent runs are faster due to the file system's buffer cache. However, on a low-RAM machine, thrashing is a possibility.

The following output show a failed workflow after no more jobs from it exist. Please note how no active jobs are shown, and the failure status of the total workflow.

```
$ pegasus-status work/submit
(no matching jobs found in Condor Q)
UNREADY  READY    PRE  QUEUED    POST SUCCESS FAILURE %DONE
      20      0      0      0      0      0      2  0.0
Summary: 1 DAG total (Failure:1)
```

pegasus-analyzer

Pegasus-analyzer is a command-line utility for parsing several files in the workflow directory and summarizing useful information to the user. It should be used after the workflow has already finished execution. pegasus-analyzer quickly goes through the jobstate.log file, and isolates jobs that did not complete successfully. It then parses their submit, and kickstart output files, printing to the user detailed information for helping the user debug what happened to his/her workflow.

The simplest way to invoke pegasus-analyzer is to simply give it a workflow run directory, like in the example below:

```
$ pegasus-analyzer /home/user/run0004
pegasus-analyzer: initializing...

*****Summary*****

Total jobs      :      26 (100.00%)
# jobs succeeded :      25 (96.15%)
# jobs failed   :       1 (3.84%)
# jobs unsubmitted :      0 (0.00%)

*****Failed jobs' details*****

2009-02-20 16:25:13.468 WARN  [root] non-zero exit-code 1
```

In the case above, pegasus-analyzer's output contains a brief summary section, showing how many jobs have succeeded and how many have failed. After that, pegasus-analyzer will print information about each job that failed, showing its last known state, along with the location of its submit, output, and error files. pegasus-analyzer will also display any stdout and stderr from the job, as recorded in its kickstart record. Please consult pegasus-analyzer's man page for more examples and a detailed description of its various command-line options.

Note

Starting with 4.0 release, by default pegasus analyzer queries the database to debug the workflow. If you want it to use files in the submit directory , use the **--files** option.

pegasus-remove

If you want to abort your workflow for any reason you can use the pegasus-remove command listed in the output of pegasus-run invocation or by specifying the Dag directory for the workflow you want to terminate.

```
$ pegasus-remove /PATH/To/WORKFLOW DIRECTORY
```

Resubmitting failed workflows

Pegasus will remove the DAGMan and all the jobs related to the DAGMan from the condor queue. A rescue DAG will be generated in case you want to resubmit the same workflow and continue execution from where it last stopped. A rescue DAG only skips jobs that have completely finished. It does not continue a partially running job unless the executable supports checkpointing.

To resubmit an aborted or failed workflow with the same submit files and rescue Dag just rerun the pegasus-run command

```
$ pegasus-run /Path/To/Workflow/Directory
```

Plotting and Statistics

Pegasus plotting and statistics tools queries the Stampede database created by pegasus-monitord for generating the output. The stampede scheme can be found [here](#).

The statistics and plotting tools use the following terminology for defining tasks, jobs etc. Pegasus takes in a DAX which is composed of tasks. Pegasus plans it into a Condor DAG / Executable workflow that consists of Jobs. In case of Clustering, multiple tasks in the DAX can be captured into a single job in the Executable workflow. When DAGMan executes a job, a job instance is populated . Job instances capture information as seen by DAGMan. In case DAGMan retires a job on detecting a failure , a new job instance is populated. When DAGMan finds a job instance has finished , an invocation is associated with job instance. In case of clustered job, multiple invocations will be associated with a single job instance. If a Pre script or Post Script is associated with a job instance, then invocations are populated in the database for the corresponding job instance.

pegasus-statistics

Pegasus statistics can compute statistics over one or more than one workflow run.

Command to generate statistics over a single run is as shown below.

```
$ pegasus-statistics /scratch/grid-setup/run0001/ -s all
```

```
#
# Pegasus Workflow Management System - http://pegasus.isi.edu
#
# Workflow summary:
# Summary of the workflow execution. It shows total
# tasks/jobs/sub workflows run, how many succeeded/failed etc.
# In case of hierarchical workflow the calculation shows the
# statistics across all the sub workflows. It shows the following
# statistics about tasks, jobs and sub workflows.
# * Succeeded - total count of succeeded tasks/jobs/sub workflows.
# * Failed - total count of failed tasks/jobs/sub workflows.
# * Incomplete - total count of tasks/jobs/sub workflows that are
# not in succeeded or failed state. This includes all the jobs
# that are not submitted, submitted but not completed etc. This
# is calculated as difference between 'total' count and sum of
# 'succeeded' and 'failed' count.
# * Total - total count of tasks/jobs/sub workflows.
```

```

#      * Retries - total retry count of tasks/jobs/sub workflows.
#      * Total+Retries - total count of tasks/jobs/sub workflows executed
#      during workflow run. This is the cumulative of retries,
#      succeeded and failed count.
# Workflow wall time:
#      The walltime from the start of the workflow execution to the end as
#      reported by the DAGMAN.In case of rescue dag the value is the
#      cumulative of all retries.
# Workflow cumulative job wall time:
#      The sum of the walltime of all jobs as reported by kickstart.
#      In case of job retries the value is the cumulative of all retries.
#      For workflows having sub workflow jobs (i.e SUBDAG and SUBDAX jobs),
#      the walltime value includes jobs from the sub workflows as well.
# Cumulative job walltime as seen from submit side:
#      The sum of the walltime of all jobs as reported by DAGMan.
#      This is similar to the regular cumulative job walltime, but includes
#      job management overhead and delays. In case of job retries the value
#      is the cumulative of all retries. For workflows having sub workflow
#      jobs (i.e SUBDAG and SUBDAX jobs), the walltime value includes jobs
#      from the sub workflows as well.
-----
Type           Succeeded Failed Incomplete Total    Retries Total+Retries
Tasks          4         0         0         4         0         4
Jobs           17         0         0        17         0        17
Sub-Workflows  0         0         0         0         0         0
-----

Workflow wall time           : 5 mins, 18 secs
Workflow cumulative job wall time : 4 mins, 2 secs
Cumulative job walltime as seen from submit side : 4 mins, 10 secs

```

By default the output gets generated to a statistics folder inside the submit directory. The output that is generated by pegasus-statistics is based on the value set for command line option 's'(statistics_level). In the sample run the command line option 's' is set to 'all' to generate all the statistics information for the workflow run. Please consult the pegasus-statistics man page to find a detailed description of various command line options.

Note

In case of hierarchal workflows, the metrics that are displayed on stdout take into account all the jobs/tasks/ sub workflows that make up the workflow by recursively iterating through each sub workflow.

Command to generate statistics over all workflow runs populated in a single database is as shown below.

```

$ pegasus-statistics -Dpegasus.monitord.output='mysql://s_user:s_user123@127.0.0.1:3306/stampede' -
o /scratch/workflow_1_2/statistics -s all --multiple-wf

```

```

#
# Pegasus Workflow Management System - http://pegasus.isi.edu
#
# Workflow summary:
# Summary of the workflow execution. It shows total
# tasks/jobs/sub workflows run, how many succeeded/failed etc.

Jobs          34         0         0        34         0        34
Sub-Workflows  0         0         0         0         0         0
-----

Workflow cumulative job wall time           : 8 mins, 5 secs
Cumulative job walltime as seen from submit side : 8 mins, 35 secs
```

Note

When computing statistics over multiple workflows, please note,

1. All workflow run information should be populated in a single STAMPEDE database.
2. The `--output` argument must be specified.
3. Job statistics information is not computed.
4. Workflow wall time information is not computed.

Pegasus statistics can also compute statistics over a few specified workflow runs, by specifying the either the submit directories, or the workflow UUIDs.

```
pegasus-statistics -Dpegasus.monitorord.output='<DB_URL>' -o <OUTPUT_DIR> <SUBMIT_DIR_1>
<SUBMIT_DIR_2> .. <SUBMIT_DIR_n>
```

OR

```
pegasus-statistics -Dpegasus.monitorord.output='<DB_URL>' -o <OUTPUT_DIR> --isuuid <UUID_1>
<UUID_2> .. <UUID_n>
```

pegasus-statistics summary which is printed on the stdout contains the following information.

- **Workflow summary** - Summary of the workflow execution. In case of hierarchical workflow the calculation shows the statistics across all the sub workflows. It shows the following statistics about tasks, jobs and sub workflows.
 - **Succeeded** - total count of succeeded tasks/jobs/sub workflows.
 - **Failed** - total count of failed tasks/jobs/sub workflows.
 - **Incomplete** - total count of tasks/jobs/sub workflows that are not in succeeded or failed state. This includes all the jobs that are not submitted, submitted but not completed etc. This is calculated as difference between 'total' count and sum of 'succeeded' and 'failed' count.
 - **Total** - total count of tasks/jobs/sub workflows.
 - **Retries** - total retry count of tasks/jobs/sub workflows.
 - **Total Run** - total count of tasks/jobs/sub workflows executed during workflow run. This is the cumulative of total retries, succeeded and failed count.
- **Workflow wall time** - The walltime from the start of the workflow execution to the end as reported by the DAGMAN. In case of rescue dag the value is the cumulative of all retries.

- **Workflow cumulate job wall time** - The sum of the walltime of all jobs as reported by kickstart. In case of job retries the value is the cumulative of all retries. For workflows having sub workflow jobs (i.e SUBDAG and SUBDAX jobs), the walltime value includes jobs from the sub workflows as well. This value is multiplied by the multiplier_factor in the job instance table.
- **Cumulative job walltime as seen from submit side** - The sum of the walltime of all jobs as reported by DAGMan. This is similar to the regular cumulative job walltime, but includes job management overhead and delays. In case of job retries the value is the cumulative of all retries. For workflows having sub workflow jobs (i.e SUBDAG and SUBDAX jobs), the walltime value includes jobs from the sub workflows. This value is multiplied by the multiplier_factor in the job instance table.

pegasus-statistics generates the following statistics files based on the command line options set.

Workflow statistics file per workflow [workflow.txt]

Workflow statistics file per workflow contains the following information about each workflow run. In case of hierarchical workflows, the file contains a table for each sub workflow. The file also contains a 'Total' table at the bottom which is the cumulative of all the individual statistics details.

A sample table is shown below. It shows the following statistics about tasks, jobs and sub workflows.

- **Workflow retries** - number of times a workflow was retried.
- **Succeeded** - total count of succeeded tasks/jobs/sub workflows.
- **Failed** - total count of failed tasks/jobs/sub workflows.
- **Incomplete** - total count of tasks/jobs/sub workflows that are not in succeeded or failed state. This includes all the jobs that are not submitted, submitted but not completed etc. This is calculated as difference between 'total' count and sum of 'succeeded' and 'failed' count.
- **Total** - total count of tasks/jobs/sub workflows.
- **Retries** - total retry count of tasks/jobs/sub workflows.
- **Total Run** - total count of tasks/jobs/sub workflows executed during workflow run. This is the cumulative of total retries, succeeded and failed count.

Table 8.1. Workflow Statistics

#	Type	Succeeded	Failed	Incomplete	Total	Retries	Total Run	Workflow Retries
2a6df11b-9972-4ba0-b4ba-4fd39c357af4								0
	Tasks	4	0	0	4	0	4	
	Jobs	13	0	0	13	0	13	
	Sub Workflows	0	0	0	0	0	0	

Job statistics file per workflow [jobs.txt]

Job statistics file per workflow contains the following details about the job instances in each workflow. A sample file is shown below.

- **Job** - the name of the job instance
- **Try** - the number representing the job instance run count.
- **Site** - the site where the job instance ran.
- **Kickstart(sec.)** - the actual duration of the job instance in seconds on the remote compute node.
- **Mult** - multiplier factor from the job instance table for the job.

- **Kickstart_Mult** - value of the Kickstart column multiplied by Mult.
- **CPU-Time** - remote CPU time computed as the stime + utime (when Kickstart is not used, this is empty).
- **Post(sec.)** - the postscript time as reported by DAGMan.
- **CondorQTime(sec.)** - the time between submission by DAGMan and the remote Grid submission. It is an estimate of the time spent in the condor q on the submit node .
- **Resource(sec.)** - the time between the remote Grid submission and start of remote execution . It is an estimate of the time job instance spent in the remote queue .
- **Runtime(sec.)** - the time spent on the resource as seen by Condor DAGMan . Is always \geq kickstart .
- **Seqexec(sec.)** - the time taken for the completion of a clustered job instance .
- **Seqexec-Delay(sec.)** - the time difference between the time for the completion of a clustered job instance and sum of all the individual tasks kickstart time .

Table 8.2. Job statistics

	Job	Try	Site	Kick-start	Mult	Kickstart_Mult	CPU-Time	Post	CondorQ-Time	Resource	Run-time	Seqexec	Seqexec-Delay
analyze_ID00000004			local	60.002	1	60.002	59.843	5.0	0.0	-	62.0	-	-

Transformation statistics file per workflow [breakdown.txt]

Transformation statistics file per workflow contains information about the invocations in each workflow grouped by transformation name. A sample file is shown below.

- **Transformation** - name of the transformation.
- **Count** - the number of times invocations with a given transformation name was executed.
- **Succeeded** - the count of succeeded invocations with a given logical transformation name .
- **Failed** - the count of failed invocations with a given logical transformation name .
- **Min (sec.)** - the minimum runtime value of invocations with a given logical transformation name times the multiplier_factor.
- **Max (sec.)** - the minimum runtime value of invocations with a given logical transformation name times the multiplier_factor.
- **Mean (sec.)** - the mean of the invocation runtimes with a given logical transformation name times the multiplier_factor.

- **Total (sec.)** - the cumulative of runtime value of invocations with a given logical transformation name times the multiplier_factor.

Table 8.3. Transformation Statistics

Transformation	Count	Succeeded	Failed	Min	Max	Mean	Total
dagman::post	13	13	0	5.0	7.0	5.231	68.0
diamond::analyze	1	1	0	60.002	60.002	60.002	60.002
diamond::findrange	2	2	0	600.01	600.02	600.02	1200.03
diamond::preprocess	1	1	0	60.002	60.002	60.002	60.002
pegasus::dirmanager	1	1	0	0.027	0.027	0.027	0.027
pegasus::pegasus-transfer	5	5	0	0.139	0.39	0.197	0.986
pegasus::rc-client	3	3	0	0.338	0.459	0.382	1.145

Time statistics file [time.txt]

Time statistics file contains job instance and invocation statistics information grouped by time and host. The time grouping can be on day/hour. The file contains the following tables Job instance statistics per day/hour, Invocation statistics per day/hour, Job instance statistics by host per day/hour and Invocation by host per day/hour. A sample Invocation statistics by host per day table is shown below.

- **Job instance statistics per day/hour** - the number of job instances run, total runtime sorted by day/hour.
- **Invocation statistics per day/hour** - the number of invocations , total runtime sorted by day/hour.
- **Job instance statistics by host per day/hour** - the number of job instances run, total runtime on each host sorted by day/hour.
- **Invocation statistics by host per day/hour** - the number of invocations , total runtime on each host sorted by day/hour.

Table 8.4. Invocation statistics by host per day

Date [YYYY-MM-DD]	Host	Count	Runtime (Sec.)
2011-07-15	butterfly.isi.edu	54	625.094

pegasus-plots

Pegasus-plots generates graphs and charts to visualize workflow execution. To generate graphs and charts run the command as shown below.

```
$ pegasus-plots -p all /scratch/grid-setup/run0001/
```

```
...
```

```
***** SUMMARY *****
```

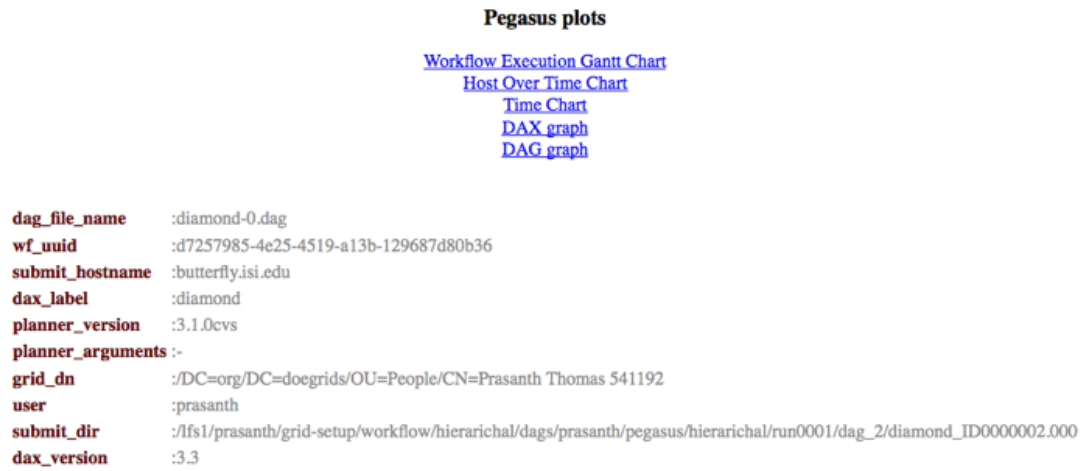

Graphs and charts generated by pegasus-plots can be viewed by opening the generated html file in the web browser :

```
/scratch/grid-setup/run0001/plots/index.html
```

```
*****
```

By default the output gets generated to plots folder inside the submit directory. The output that is generated by pegasus-plots is based on the value set for command line option 'p'(plotting_level).In the sample run the command line option 'p' is set to 'all' to generate all the charts and graphs for the workflow run. Please consult the pegasus-plots man page to find a detailed description of various command line options.pegasus-plots generates an index.html file which provides links to all the generated charts and plots. A sample index.html page is show below.

Figure 8.1. pegasus-plot index page

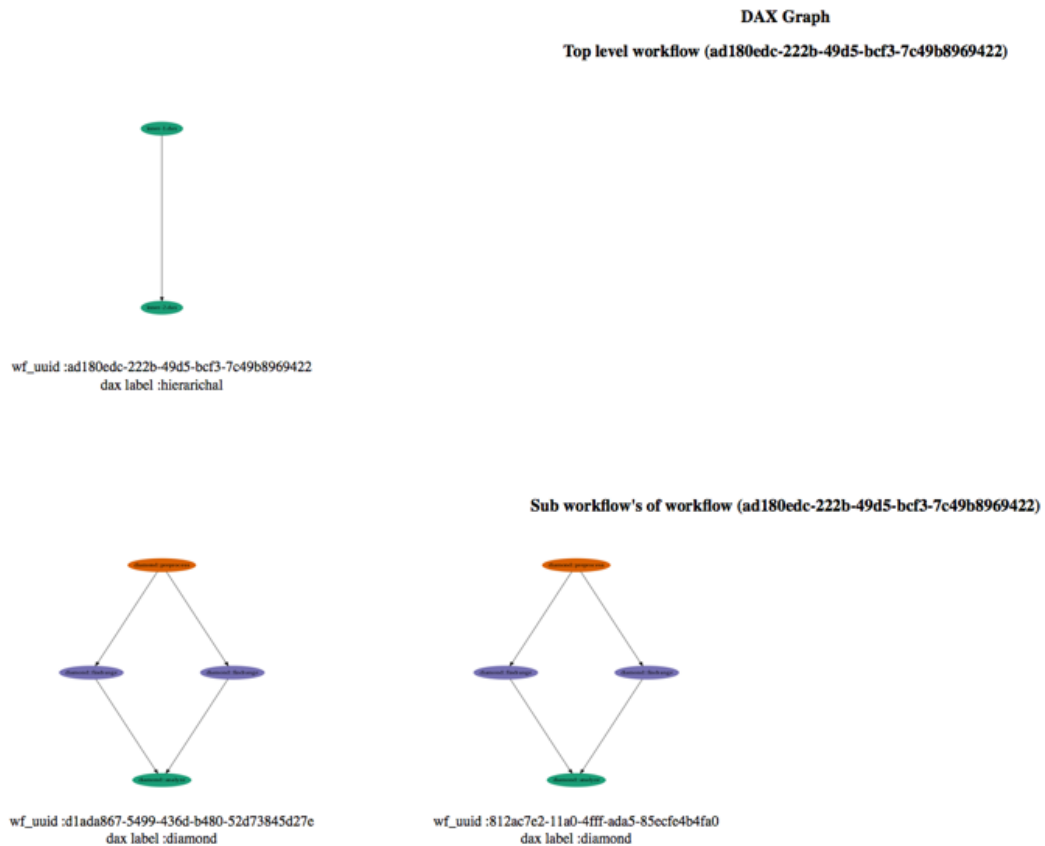

pegasus-plots generates the following plots and charts.

Dax Graph

Graph representation of the DAX file. A sample page is shown below.

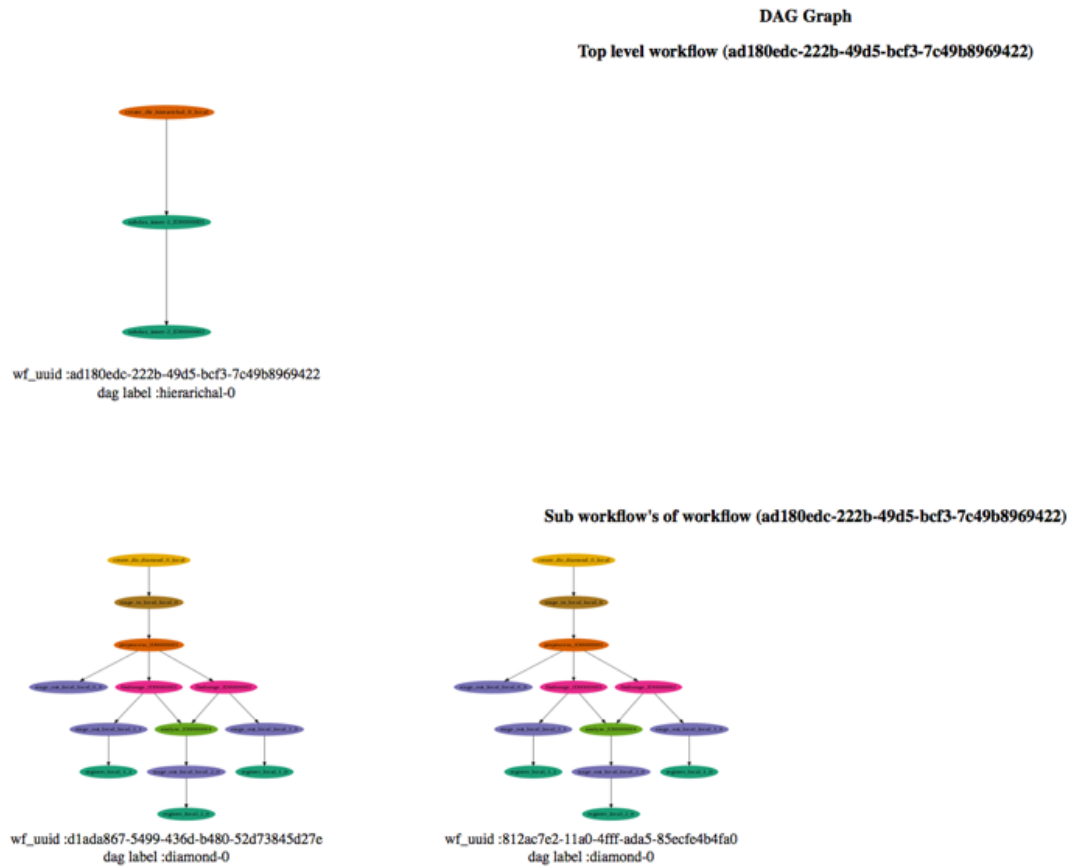

Figure 8.2. DAX Graph

Dag Graph

Graph representation of the DAG file. A sample page is shown below.

Figure 8.3. DAG Graph

Gantt workflow execution chart

Gantt chart of the workflow execution run. A sample page is shown below.

Figure 8.4. Gantt Chart

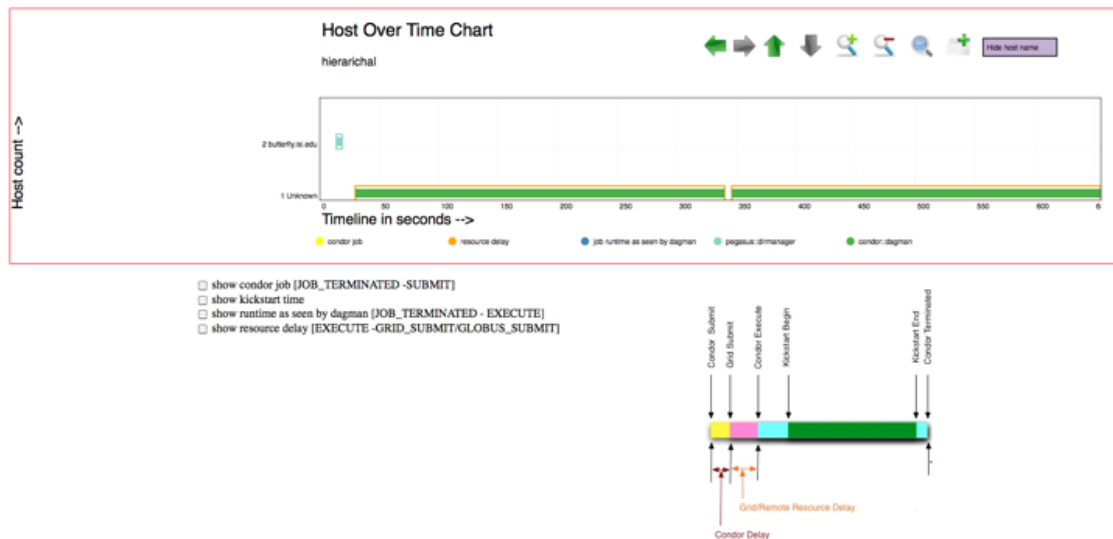

The toolbar at the top provides zoom in/out , pan left/right/top/bottom and show/hide job name functionality. The toolbar at the bottom can be used to show/hide job states. Failed job instances are shown in red border in the chart. Clicking on a sub workflow job instance will take you to the corresponding sub workflow chart.

Host over time chart

Host over time chart of the workflow execution run. A sample page is shown below.

Figure 8.5. Host over time chart

The toolbar at the top provides zoom in/out , pan left/right/top/bottom and show/hide host name functionality. The toolbar at the bottom can be used to show/hide job states. Failed job instances are shown in red border in the chart. Clicking on a sub workflow job instance will take you to the corresponding sub workflow chart.

Time chart

Time chart shows job instance/invocation count and runtime of the workflow run over time. A sample page is shown below.

Figure 8.6. Time chart

The toolbar at the top provides zoom in/out and pan left/right/top/bottom functionality. The toolbar at the bottom can be used to switch between job instances/ invocations and day/hour filtering.

Breakdown chart

Breakdown chart shows invocation count and runtime of the workflow run grouped by transformation name. A sample page is shown below.

Figure 8.7. Breakdown chart

The toolbar at the bottom can be used to switch between invocation count and runtime filtering. Legends can be clicked to get more details.

Dashboard

As the number of jobs and tasks in workflows increase, the ability to track the progress and quickly debug a workflow becomes more and more important. The dashboard provides users with a tool to monitor and debug workflows both in real-time as well as after execution is already completed, through a browser.

Workflow Dashboard

Pegasus Workflow Dashboard is bundled with the Pegasus service layer. This is available as a separate project in Github [<https://github.com/pegasus-isi/pegasus-service>]. The pegasus-service-server is developed in Python and uses the Flask framework to implement the web interface. The users can then connect to this server using a browser to monitor/debug workflows.

Note

the workflow dashboard can only monitor workflows which have been executed using Pegasus 4.2.0 and above.

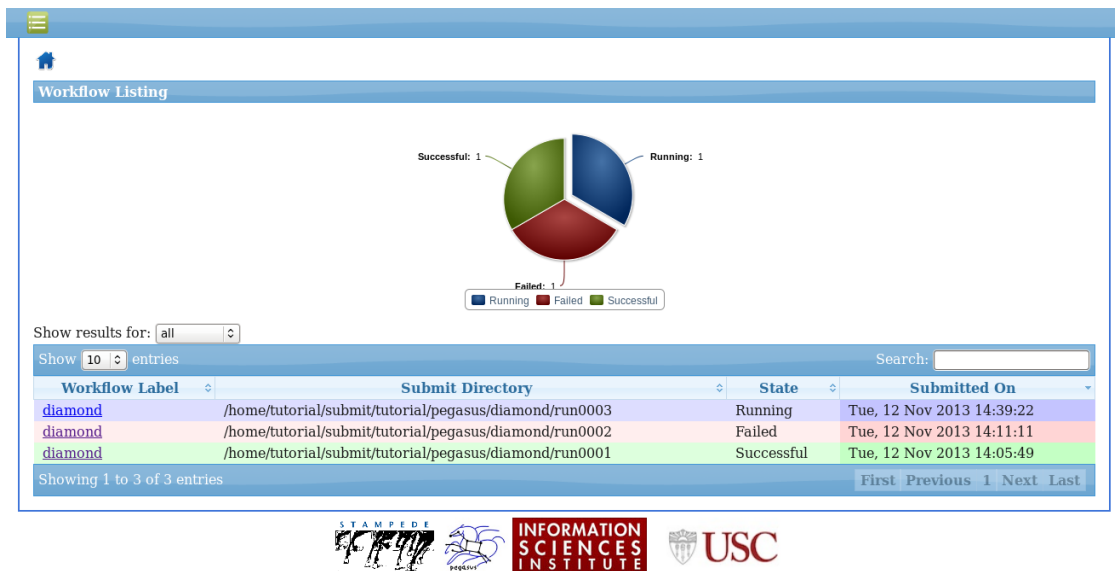

By default, the server is configured to listen on all network interfaces on port 5000. A user can view the dashboard on http://<IP_ADDRESS>:5000/

By default, the dashboard server can only monitor workflows run by the current user i.e. the user who is running the pegasus-service-server.

The Dashboard's home page lists all workflows, which have been run by the current-user. The home page shows the status of each of the workflow i.e. Running/Successful/Failed. The home page lists only the top level workflows (Pegasus supports hierarchical workflows i.e. workflows within a workflow). The rows in the table are color coded

- **Green:** indicates workflow finished successfully.
- **Red:** indicates workflow finished with a failure.
- **Blue:** indicates a workflow is currently running.

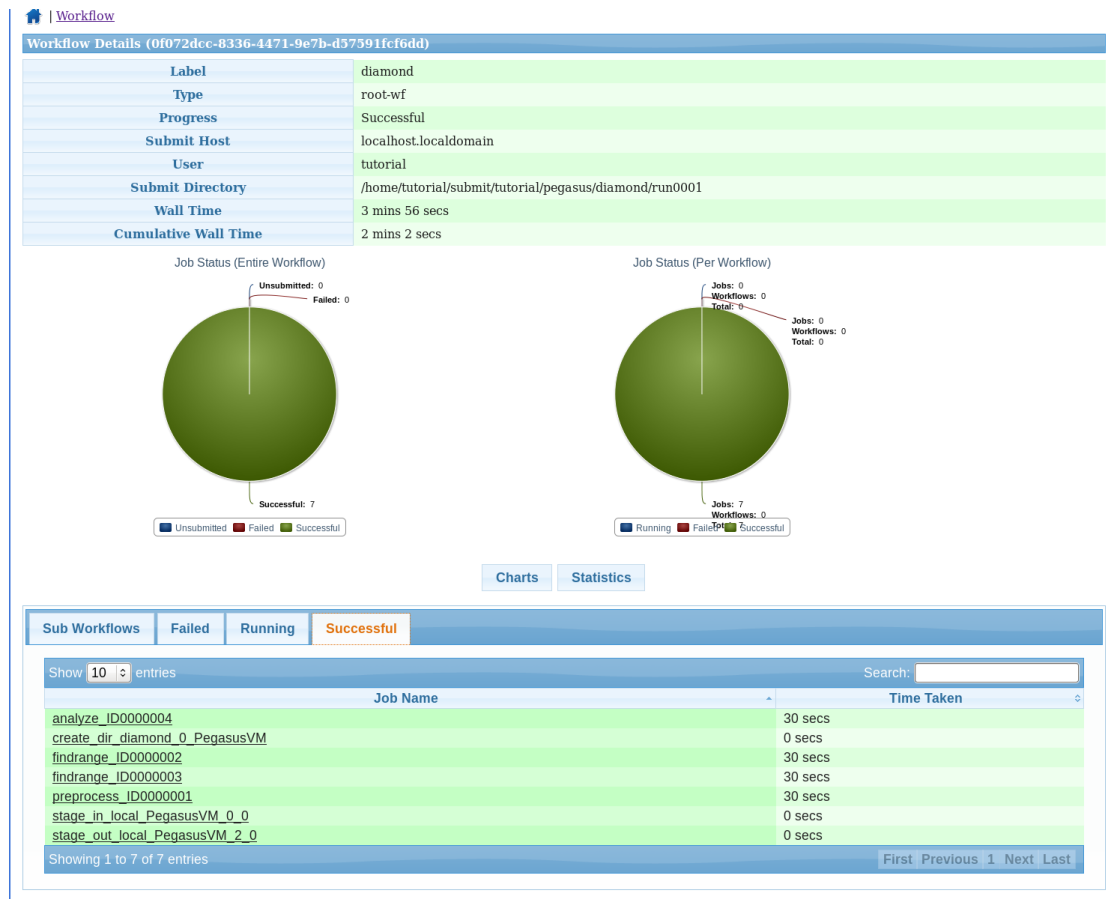

Figure 8.8. Dashboard Home Page

To view details specific to a workflow, the user can click on corresponding workflow label. The workflow details page lists workflow specific information like workflow label, workflow status, location of the submit directory, etc. The details page also displays pie charts showing the distribution of jobs based on status.

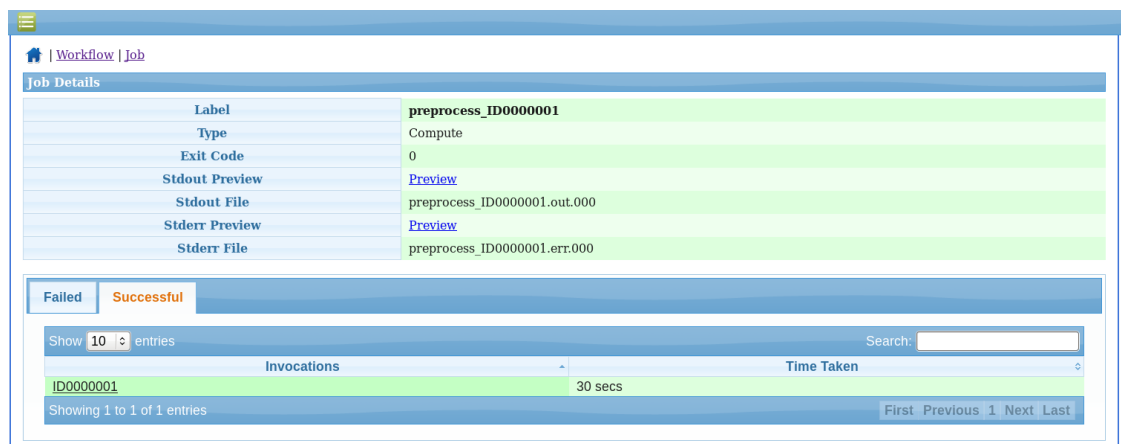

In addition, the details page displays a tab listing all sub-workflows and their statuses. Additional tabs exist which list information for all running, failed, and successful jobs.

The information displayed for a job depends on its status. For example, the failed jobs tab displays the job name, exit code, links to available standard output, and standard error contents.

Figure 8.9. Dashboard Workflow Page

To view details specific to a job the user can click on the corresponding job's job label. The job details page lists information relevant to a specific job. For example, the page lists information like job name, exit code, run time, etc.

The job details page also shows tabs for failed, and successful task invocations (Pegasus allows users to group multiple smaller task's into a single job i.e. a job may consist of one or more tasks)

Figure 8.10. Dashboard Job Description Page

The task invocation details page provides task specific information like task name, exit code, duration etc. Task details differ from job details, as they are more granular in nature.

Figure 8.11. Dashboard Invocation Page

Workflow Job Task	
Invocation Details	
Task Label	ID0000001
Transformation	preprocess
Executable	/home/tutorial/bin/transformation.py
Arguments	-i f.a -o f.b1 -o f.b2
Exit Code	0
Start Time	Tue, 12 Nov 2013 14:07:08
Remote Duration	30 secs
Remote CPU Time	0 secs

The dashboard also has web pages for workflow statistics and workflow charts, which graphically renders information provided by the pegasus-statistics and pegasus-plots command respectively.

The Statistics page shows the following statistics.

1. Workflow level statistics
2. Job breakdown statistics
3. Job specific statistics

Job Breakdown Statistics

Job Statistics

The Charts page shows the following charts.

1. Job Distribution by Count/Time
2. Time Chart by Job/Invocation
3. Workflow Execution Gantt Chart

The chart below shows the invocation distribution by count or time.

Figure 8.13. Dashboard Plots - Job Distribution

The time chart shown below shows the number of jobs/invocations in the workflow and their total runtime

Figure 8.14. Dashboard Plots - Time Chart

The workflow gantt chart lays out the execution of the jobs in the workflow over time.

Figure 8.15. Dashboard Plots - Workflow Gantt Chart

Chapter 9. Example Workflows

These examples are included in the Pegasus distribution and can be found under `share/pegasus/examples` in your Pegasus install (`/usr/share/pegasus/examples` for native packages)

Note

These examples are intended to be a starting point for when you want to create your own workflows and want to see how other workflows are set up. The example workflows will probably not work in your environment without modifications. Site and transformation catalogs contain site and user specifics such as paths to scratch directories and installed software, and at least minor modifications are required to get the workflows to plan and run.

Grid Examples

These examples assumes you have access to a cluster with Globus installed. A pre-ws gatekeeper and gridftp server is required. You also need Globus and Pegasus installed, both on the machine you are submitting from, and the cluster.

Black Diamond

Pegasus is shipped with 3 different Black Diamond examples for the grid. This is to highlight the available DAX APIs which are Java, Perl and Python. The examples can be found under:

```
share/pegasus/examples/grid-blackdiamond-java/  
share/pegasus/examples/grid-blackdiamond-perl/  
share/pegasus/examples/grid-blackdiamond-python/
```

The workflow has 4 nodes, layed out in a diamond shape, with files being passed between them (f.*):

The binary for the nodes is a simple "mock application" name **keg** ("canonical example for the grid") which reads input files designated by arguments, writes them back onto output files, and produces on STDOUT a summary of where and when it was run. Keg ships with Pegasus in the bin directory.

This example ships with a "submit" script which will build the replica catalog, the transformation catalog, and the site catalog. When you create your own workflows, such a submit script is not needed if you want to maintain those catalogs manually.

Note

The use of `./submit` scripts in these examples are just to make it more easy to run the examples out of the box. For a production site, the catalogs (transformation, replica, site) may or may not be static or generated by other tooling.

To test the examples, edit the **submit** script and change the cluster config to the setup and install locations for your cluster. Then run:

```
$ ./submit
```

The workflow should now be submitted and in the output you should see a work dir location for the instance. With that directory you can monitor the workflow with:

```
$ pegasus-status [workdir]
```

Once the workflow is done, you can make sure it was successful with:

```
$ pegasus-analyzer -d [workdir]
```

NASA/IPAC Montage

This example can be found under

```
share/pegasus/examples/grid-montage/
```

The NASA IPAC Montage (<http://montage.ipac.caltech.edu/>) workflow projects/montages a set of input images from telescopes like Hubble and end up with images like <http://montage.ipac.caltech.edu/images/m104.jpg>. The test workflow is for a 1 by 1 degrees tile. It has about 45 input images which all have to be projected, background modeled and adjusted to come out as one seamless image.

Just like the Black Diamond above, this example uses a `./submit` script.

The Montage DAX is generated with a tool called mDAG shipped with Montage which generates the workflow.

Rosetta

This example can be found under

```
share/pegasus/examples/grid-rosetta/
```

Rosetta (<http://www.rosettacommons.org/>) is a high resolution protein prediction and design software. Highlights in this example are:

- Using the Pegasus Java API to generate the DAX
- The DAX generator loops over the input PDBs and creates a job for each input
- The jobs all have a dependency on a flatfile database. For simplicity, each job depends on all the files in the database directory.
- Job clustering is turned on to make each grid job run longer and better utilize the compute cluster

Just like the Black Diamond above, this example uses a `./submit` script.

Condor Examples

Black Diamond - condorio

There are a set of Condor examples available, highlighting different data staging configurations. The most basic one is condorio, and the example can be found under:

```
share/pegasus/examples/condor-blackdiamond-condorio/
```

This example is using the same abstract workflow as the Black Diamond grid example above, and can be executed either on the submit machine (`universe="local"`) or on a local Condor pool (`universe="vanilla"`).

You can run this example with the `./submit` script. Example:

```
$ ./submit
```

Local Shell Examples

Black Diamond

To aid in workflow development and debugging, Pegasus can now map a workflow to a local shell script. One advantage is that you do not need a remote compute resource.

This example is using the same abstract workflow as the Black Diamond grid example above. The difference is that a property is set in `pegasusrc` to force shell execution:

```
# tell pegasus to generate shell version of
# the workflow
pegasus.code.generator = Shell
```

You can run this example with the `./submit` script.

Notifications Example

A new feature in Pegasus 3.1. is notifications. While the workflow is running, a monitoring tool is running side by side to the workflow, and issues user defined notifications when certain events takes place, such as job completion or failure. See notifications section for detailed information. A workflow example with notifications can be found under `examples/notifications`. This workflow is based on the Black Diamond, with the changes being notifications added to the DAX generator. For example, notifications are added at the workflow level:

```
# Create a abstract dag
diamond = ADAG("diamond")
# dax level notifications
diamond.invoke('all', os.getcwd() + "/my-notify.sh")
```

The DAX generator also contains job level notifications:

```
# job level notifications - in this case for at_end events
frr.invoke('at_end', os.getcwd() + "/my-notify.sh")
```

These invoke lines specify that the **my-notify.sh** script will be invoked for events generated (**all** in the first case, **at_end** in the second). The **my-notify.sh** script contains callouts sample notification tools shipped with Pegasus, one for email and for Jabber/GTalk (commented out by default):

```
#!/bin/bash

# Pegasus ships with a couple of basic notification tools. Below
# we show how to notify via email and gtalk.

# all notifications will be sent to email
# change $USER to your full email address
$PEGASUS_HOME/libexec/notification/email -t $USER

# this sends notifications about failed jobs to gtalk.
# note that you can also set which events to trigger on in your DAX.
# set jabberid to your gmail address, and put in your
# password
# uncomment to enable
if [ "$PEGASUS_STATUS" != "x" -a "$PEGASUS_STATUS" != "0" ]; then
    $PEGASUS_HOME/libexec/notification/jabber --jabberid FIXME@gmail.com \
        --password FIXME \
        --host talk.google.com
fi
```

Workflow of Workflows

Galactic Plane

The Galactic Plane [http://en.wikipedia.org/wiki/Galactic_plane] workflow is a workflow of many Montage workflows. The output is a set of tiles which can be used in software which takes the tiles and produces a seamless image

which can be scrolled and zoomed into. As this is more of a production workflow than an example one, it can be a little bit harder to get running in your environment.

Highlights of the example are:

- The subworkflow DAXes are generated as jobs in the parent workflow - this is an example on how to make more dynamic workflows. For example, if you need a job in your workflow to determine the number of jobs in the next level, you can have the first job create a subworkflow with the right number of jobs.
- DAGMan job categories are used to limit the number of concurrent jobs in certain places. This is used to limit the number of concurrent connections to the data find service, as well limit the number of concurrent subworkflows to manage disk usage on the compute cluster.
- Job priorities are used to make sure we overlap staging and computation. Pegasus sets default priorities, which for most jobs are fine, but the priority of the data find job is set explicitly to a higher priority.
- A specific output site is defined in the site catalog and specified with the --output option of subworkflows.

The DAX API has support for sub workflows:

```
remote_tile_setup = Job(namespace="gp", name="remote_tile_setup", version="1.0")
remote_tile_setup.addArguments("%05d" % (tile_id))
remote_tile_setup.addProfile(Profile("dagman", "CATEGORY", "remote_tile_setup"))
remote_tile_setup.uses(params, link=Link.INPUT, register=False)
remote_tile_setup.uses(mdagtar, link=Link.OUTPUT, register=False, transfer=True)
uber dax.addJob(remote_tile_setup)

...
subwf = DAX("%05d.dax" % (tile_id), "ID%05d" % (tile_id))
subwf.addArguments("-Dpegasus.schema.dax=%s/etc/dax-2.1.xsd" % (os.environ["PEGASUS_HOME"]),
                  "-Dpegasus.catalog.replica.file=%s/rc.data" % (tile_work_dir),
                  "-Dpegasus.catalog.site.file=%s/sites.xml" % (work_dir),
                  "-Dpegasus.transfer.links=true",
                  "--sites", cluster_name,
                  "--cluster", "horizontal",
                  "--basename", "tile-%05d" % (tile_id),
                  "--force",
                  "--output", output_name)
subwf.addProfile(Profile("dagman", "CATEGORY", "subworkflow"))
subwf.uses(subdax_file, link=Link.INPUT, register=False)
uber dax.addDAX(subwf)
```

Chapter 10. Reference Manual

Properties

This is the reference guide to all properties regarding the Pegasus Workflow Planner, and their respective default values. Please refer to the user guide for a discussion when and which properties to use to configure various components. Please note that the values rely on proper capitalization, unless explicitly noted otherwise.

Some properties rely with their default on the value of other properties. As a notation, the curly braces refer to the value of the named property. For instance, `${pegasus.home}` means that the value depends on the value of the `pegasus.home` property plus any noted additions. You can use this notation to refer to other properties, though the extent of the substitutions are limited. Usually, you want to refer to a set of the standard system properties. Nesting is not allowed. Substitutions will only be done once.

There is a priority to the order of reading and evaluating properties. Usually one does not need to worry about the priorities. However, it is good to know the details of when which property applies, and how one property is able to overwrite another. The following is a mutually exclusive list (highest priority first) of property file locations.

1. `--conf` option to the tools. Almost all of the clients that use properties have a `--conf` option to specify the property file to pick up.
2. `submit-dir/pegasus.xxxxxxx.properties` file. All tools that work on the submit directory (i.e after pegasus has planned a workflow) pick up the `pegasus.xxxxx.properties` file from the submit directory. The location for the `pegasus.xxxxxxx.properties` is picked up from the `braindump` file.
3. The properties defined in the user property file `${user.home}/.pegasusrc` have lowest priority.

Commandline properties have the highest priority. These override any property loaded from a property file. Each commandline property is introduced by a `-D` argument. Note that these arguments are parsed by the shell wrapper, and thus the `-D` arguments must be the first arguments to any command. Commandline properties are useful for debugging purposes.

From Pegasus 3.1 release onwards, support has been dropped for the following properties that were used to signify the location of the properties file

- `pegasus.properties`
- `pegasus.user.properties`

The following example provides a sensible set of properties to be set by the user property file. These properties use mostly non-default settings. It is an example only, and will not work for you:

<code>pegasus.catalog.replica</code>	File
<code>pegasus.catalog.replica.file</code>	<code>\${pegasus.home}/etc/sample.rc.data</code>
<code>pegasus.catalog.transformation</code>	Text
<code>pegasus.catalog.transformation.file</code>	<code>\${pegasus.home}/etc/sample.tc.text</code>
<code>pegasus.catalog.site.file</code>	<code>\${pegasus.home}/etc/sample.sites.xml</code>

If you are in doubt which properties are actually visible, pegasus during the planning of the workflow dumps all properties after reading and prioritizing in the submit directory in a file with the suffix properties.

pegasus.home

Systems:	all
Type:	directory location string
Default:	"\$PEGASUS_HOME"

The property `pegasus.home` cannot be set in the property file. This property is automatically set up by the pegasus clients internally by determining the installation directory of pegasus. Knowledge about this property is important for developers who want to invoke PEGASUS JAVA classes without the shell wrappers.

Local Directories

This section describes the GNU directory structure conventions. GNU distinguishes between architecture independent and thus sharable directories, and directories with data specific to a platform, and thus often local. It also distinguishes between frequently modified data and rarely changing data. These two axis form a space of four distinct directories.

pegasus.home.datadir

Systems:	all
Type:	directory location string
Default:	<code>\${pegasus.home}/share</code>

The datadir directory contains broadly visible and possibly exported configuration files that rarely change. This directory is currently unused.

pegasus.home.sysconfdir

Systems:	all
Type:	directory location string
Default:	<code>\${pegasus.home}/etc</code>

The system configuration directory contains configuration files that are specific to the machine or installation, and that rarely change. This is the directory where the XML schema definition copies are stored, and where the base pool configuration file is stored.

pegasus.home.sharedstatedir

Systems:	all
Type:	directory location string
Default:	<code>\${pegasus.home}/com</code>

Frequently changing files that are broadly visible are stored in the shared state directory. This is currently unused.

pegasus.home.localstatedir

Systems:	all
Type:	directory location string
Default:	<code>\${pegasus.home}/var</code>

Frequently changing files that are specific to a machine and/or installation are stored in the local state directory. This directory is being used for the textual transformation catalog, and the file-based replica catalog.

pegasus.dir.submit.logs

System:	Pegasus
---------	---------

Since:	2.4
Type:	directory location string

This property can be used to specify the directory where the condor logs for the workflow should go to. By default, starting 4.2.1 release, Pegasus will setup the log to be in the workflow submit directory. This can create problems, in case users submit directories are on NSF.

This is done to ensure that the logs are created in a local directory even though the submit directory maybe on NFS.

Site Directories

The site directory properties modify the behavior of remotely run jobs. In rare occasions, it may also pertain to locally run compute jobs.

pegasus.dir.useTimestamp

System:	Pegasus
Since:	2.1
Type:	Boolean
Default:	false

While creating the submit directory, Pegasus employs a run numbering scheme. Users can use this property to use a timestamp based numbering scheme instead of the runxxxx scheme.

pegasus.dir.exec

System:	Pegasus
Since:	2.0
Type:	remote directory location string
Default:	(no default)

This property modifies the remote location work directory in which all your jobs will run. If the path is relative then it is appended to the work directory (associated with the site), as specified in the site catalog. If the path is absolute then it overrides the work directory specified in the site catalog.

pegasus.dir.storage.mapper

System:	Pegasus
Since:	4.3
Type:	enumeration
Value[0]:	Flat
Value[1]:	Fixed
Value[2]:	Hashed
Value[3]:	Replica
Default:	Flat
See Also:	pegasus.dir.storage.deep

This property modifies determines how the output files are mapped on the output site storage location.

In order to preserve backward compatibility, setting the boolean property `pegasus.dir.storage.deep` results in the Hashed output mapper to be loaded, if no output mapper property is specified.

Flat By default, Pegasus will place the output files in the storage directory specified in the site catalog for the output site.

Fixed Using this mapper, users can specify an externally accessible url to the storage directory in their properties file. The following property needs to be set.

```
pegasus.dir.storage.mapper.fixed.url  an externally accessible URL to the
storage directory on the output site
e.g. gsiftp://outputs.isi.edu/shared/outputs
```

Note: For hierarchal workflows, the above property needs to be set separately for each dax job, if you want the sub workflow outputs to goto a different directory.

Hashed This mapper results in the creation of a deep directory structure on the output site, while populating the results. The base directory on the remote end is determined from the site catalog. Depending on the number of files being staged to the remote site a Hashed File Structure is created that ensures that only 256 files reside in one directory. To create this directory structure on the storage site, Pegasus relies on the directory creation feature of the Grid FTP server, which appeared in globus 4.0.x

Replica This mapper determines the path for an output file on the output site by querying an output replica catalog. The output site is one that is passed on the command line. The output replica catalog can be configured by specifying the properties with the prefix `pegasus.dir.storage.replica`. By default, a Regex File based backend is assumed unless overridden. For example

```
pegasus.dir.storage.mapper.replica      Regex|File
pegasus.dir.storage.mapper.replica.file the RC file at the backend to use if using a
file based RC
```

pegasus.dir.storage.deep

System:	Pegasus
Since:	2.1
Type:	Boolean
Default:	false
See Also:	pegasus.dir.storage.mapper

This property results in the creation of a deep directory structure on the output site, while populating the results. The base directory on the remote end is determined from the site catalog.

To this base directory, the relative submit directory structure (`$user/$vogroup/$label/runxxxx`) is appended.

`$storage = $base + $relative_submit_directory`

This is the base directory that is passed to the storage mapper.

Note: To preserve backward compatiblty, setting this property results in the Hashed mapper to be loaded unless `pegasus.dir.storage.mapper` is explicitly specified. Before 4.3, this property resulted in HashedDirectory structure.

pegasus.dir.create.strategy

System:	Pegasus
Since:	2.2
Type:	enumeration
Value[0]:	HourGlass

Value[1]:	Tentacles
Value[2]:	Minimal
Default:	Minimal

If the

`--randomdir`

option is given to the Planner at runtime, the Pegasus planner adds nodes that create the random directories at the remote pool sites, before any jobs are actually run. The two modes determine the placement of these nodes and their dependencies to the rest of the graph.

HourGlass	It adds a make directory node at the top level of the graph, and all these concat to a single dummy job before branching out to the root nodes of the original/ concrete dag so far. So we introduce a classic X shape at the top of the graph. Hence the name HourGlass.
Tentacles	This option places the jobs creating directories at the top of the graph. However instead of constricting it to an hour glass shape, this mode links the top node to all the relevant nodes for which the create dir job is necessary. It looks as if the node spreads its tentacles all around. This puts more load on the DAGMan because of the added dependencies but removes the restriction of the plan progressing only when all the create directory jobs have progressed on the remote pools, as is the case in the HourGlass model.
Minimal	The strategy involves in walking the graph in a BFS order, and updating a bit set associated with each job based on the BitSet of the parent jobs. The BitSet indicates whether an edge exists from the create dir job to an ancestor of the node. For a node, the bit set is the union of all the parents BitSets. The BFS traversal ensures that the bitsets of a node are only updated once the parents have been processed.

pegasus.dir.create.impl

System:	Pegasus
Since:	2.2
Type:	enumeration
Value[0]:	DefaultImplementation
Value[1]:	S3
Default:	DefaultImplementation

This property is used to select the executable that is used to create the working directory on the compute sites.

DefaultImplementation	The default executable that is used to create a directory is the dirmanager executable shipped with Pegasus. It is found at \$PEGASUS_HOME/bin/dirmanager in the pegasus distribution. An entry for transformation pegasus::dirmanager needs to exist in the Transformation Catalog or the PEGASUS_HOME environment variable should be specified in the site catalog for the sites for this mode to work.
S3	This option is used to create buckets in S3 instead of a directory. This should be set when running workflows on Amazon EC2. This implementation relies on s3cmd command line client to create the bucket. An entry for transformation amazon::s3cmd needs to exist in the Transformation Catalog for this to work.

Schema File Location Properties

This section defines the location of XML schema files that are used to parse the various XML document instances in the PEGASUS. The schema backups in the installed file-system permit PEGASUS operations without being online.

pegasus.schema.dax

Systems:	Pegasus
Since:	2.0
Type:	XML schema file location string
Value[0]:	\${pegasus.home.sysconfdir}/dax-3.2.xsd
Default:	\${pegasus.home.sysconfdir}/dax-3.2.xsd

This file is a copy of the XML schema that describes abstract DAG files that are the result of the abstract planning process, and input into any concrete planning. Providing a copy of the schema enables the parser to use the local copy instead of reaching out to the internet, and obtaining the latest version from the GriPhyN website dynamically.

pegasus.schema.sc

Systems:	Pegasus
Since:	2.0
Type:	XML schema file location string
Value[0]:	\${pegasus.home.sysconfdir}/sc-3.0.xsd
Default:	\${pegasus.home.sysconfdir}/sc-3.0.xsd

This file is a copy of the XML schema that describes the xml description of the site catalog, that is generated as a result of using genpoolconfig command. Providing a copy of the schema enables the parser to use the local copy instead of reaching out to the internet, and obtaining the latest version from the GriPhyN website dynamically.

pegasus.schema.ivr

Systems:	all
Type:	XML schema file location string
Value[0]:	\${pegasus.home.sysconfdir}/ivr-2.0.xsd
Default:	\${pegasus.home.sysconfdir}/ivr-2.0.xsd

This file is a copy of the XML schema that describes invocation record files that are the result of the a grid launch in a remote or local site. Providing a copy of the schema enables the parser to use the local copy instead of reaching out to the internet, and obtaining the latest version from the GriPhyN website dynamically.

Database Drivers For All Relational Catalogs

pegasus.catalog.*.db.driver

System:	Pegasus
Type:	Java class name
Value[0]:	Postgres
Value[1]:	MySQL
Value[2]:	SQLServer2000 (not yet implemented!)
Value[3]:	Oracle (not yet implemented!)

Default:	(no default)
See also:	pegasus.catalog.provenance

The database driver class is dynamically loaded, as required by the schema. Currently, only PostgreSQL 7.3 and MySQL 4.0 are supported. Their respective JDBC3 driver is provided as part and parcel of the PEGASUS.

A user may provide their own implementation, derived from `org.griphyn.vdl.dbdriver.DatabaseDriver`, to talk to a database of their choice.

For each schema in PTC, a driver is instantiated separately, which has the same prefix as the schema. This may result in multiple connections to the database backend. As fallback, the schema "*" driver is attempted.

The * in the property name can be replaced by a catalog name to apply the property only for that catalog. Valid catalog names are

```
replica
provenance
```

pegasus.catalog.*.db.url

System:	PTC, ...
Type:	JDBC database URI string
Default:	(no default)
Example:	jdbc:postgresql:\${user.name}

Each database has its own string to contact the database on a given host, port, and database. Although most driver URLs allow to pass arbitrary arguments, please use the `pegasus.catalog.[catalog-name].db.*` keys or `pegasus.catalog.*.db.*` to preload these arguments. THE URL IS A MANDATORY PROPERTY FOR ANY DBMS BACKEND.

```
Postgres : jdbc:postgresql:[//hostname[:port]/]database
MySQL    : jdbc:mysql://hostname[:port]/database
SQLServer: jdbc:microsoft:sqlserver://hostname:port
Oracle    : jdbc:oracle:thin:[user/password]@//host[:port]/service
```

The * in the property name can be replaced by a catalog name to apply the property only for that catalog. Valid catalog names are

```
replica
provenance
```

pegasus.catalog.*.db.user

System:	PTC, ...
Type:	string
Default:	(no default)
Example:	\${user.name}

In order to access a database, you must provide the name of your account on the DBMS. This property is database-independent. THIS IS A MANDATORY PROPERTY FOR MANY DBMS BACKENDS.

The * in the property name can be replaced by a catalog name to apply the property only for that catalog. Valid catalog names are

```
replica
```

provenance

pegasus.catalog.*.db.password

System:	PTC, ...
Type:	string
Default:	(no default)
Example:	\${user.name}

In order to access a database, you must provide an optional password of your account on the DBMS. This property is database-independent. THIS IS A MANDATORY PROPERTY, IF YOUR DBMS BACKEND ACCOUNT REQUIRES A PASSWORD.

The * in the property name can be replaced by a catalog name to apply the property only for that catalog. Valid catalog names are

replica
provenance

pegasus.catalog.*.db.*

System:	PTC, RC
---------	---------

Each database has a multitude of options to control in fine detail the further behaviour. You may want to check the JDBC3 documentation of the JDBC driver for your database for details. The keys will be passed as part of the connect properties by stripping the "pegasus.catalog.[catalog-name].db." prefix from them. The catalog-name can be replaced by the following values provenance for Provenance Catalog (PTC), replica for Replica Catalog (RC)

Postgres 7.3 parses the following properties:

```
pegasus.catalog.*.db.user
pegasus.catalog.*.db.password
pegasus.catalog.*.db.PGHOST
pegasus.catalog.*.db.PGPORT
pegasus.catalog.*.db.charSet
pegasus.catalog.*.db.compatible
```

MySQL 4.0 parses the following properties:

```
pegasus.catalog.*.db.user
pegasus.catalog.*.db.password
pegasus.catalog.*.db.databaseName
pegasus.catalog.*.db.serverName
pegasus.catalog.*.db.portNumber
pegasus.catalog.*.db.socketFactory
pegasus.catalog.*.db.strictUpdates
pegasus.catalog.*.db.ignoreNonTxTables
pegasus.catalog.*.db.secondsBeforeRetryMaster
pegasus.catalog.*.db.queriesBeforeRetryMaster
pegasus.catalog.*.db.allowLoadLocalInfile
pegasus.catalog.*.db.continueBatchOnError
pegasus.catalog.*.db.pedantic
pegasus.catalog.*.db.useStreamLengthsInPrepStmts
pegasus.catalog.*.db.useTimezone
pegasus.catalog.*.db.relaxAutoCommit
pegasus.catalog.*.db.paranoid
pegasus.catalog.*.db.autoReconnect
pegasus.catalog.*.db.capitalizeTypeNames
pegasus.catalog.*.db.ultraDevHack
pegasus.catalog.*.db.strictFloatingPoint
pegasus.catalog.*.db.useSSL
```

```

pegasus.catalog.*.db.useCompression
pegasus.catalog.*.db.socketTimeout
pegasus.catalog.*.db.maxReconnects
pegasus.catalog.*.db.initialTimeout
pegasus.catalog.*.db.maxRows
pegasus.catalog.*.db.useHostsInPrivileges
pegasus.catalog.*.db.interactiveClient
pegasus.catalog.*.db.useUnicode
pegasus.catalog.*.db.characterEncoding

```

MS SQL Server 2000 support the following properties (keys are case-insensitive, e.g. both "user" and "User" are valid):

```

pegasus.catalog.*.db.User
pegasus.catalog.*.db.Password
pegasus.catalog.*.db.DatabaseName
pegasus.catalog.*.db.ServerName
pegasus.catalog.*.db.HostProcess
pegasus.catalog.*.db.NetAddress
pegasus.catalog.*.db.PortNumber
pegasus.catalog.*.db.ProgramName
pegasus.catalog.*.db.SendStringParametersAsUnicode
pegasus.catalog.*.db.SelectMethod

```

The * in the property name can be replaced by a catalog name to apply the property only for that catalog. Valid catalog names are

```

replica
provenance

```

Catalog Properties

Replica Catalog

pegasus.catalog.replica

System:	Pegasus
Since:	2.0
Type:	enumeration
Value[0]:	RLS
Value[1]:	LRC
Value[2]:	JDBCRC
Value[3]:	File
Value[4]:	Directory
Value[5]:	MRC
Value[6]:	Regex
Default:	RLS

Pegasus queries a Replica Catalog to discover the physical filenames (PFN) for input files specified in the DAX. Pegasus can interface with various types of Replica Catalogs. This property specifies which type of Replica Catalog to use during the planning process.

RLS RLS (Replica Location Service) is a distributed replica catalog, which ships with GT4. There is an index service called Replica Location Index (RLI) to which 1 or more Local Replica Catalog (LRC) report. Each LRC can contain all or a subset of mappings. In this mode, Pegasus queries the central RLI to discover in which LRC's the mappings for a LFN reside. It then queries the individual LRC's for the PFN's. To use RLS, the user additionally needs to set the property `pegasus.catalog.replica.url`

to specify the URL for the RLI to query. Details about RLS can be found at <http://www.globus.org/toolkit/data/rls/>

LRC If the user does not want to query the RLI, but directly a single Local Replica Catalog. To use LRC, the user additionally needs to set the property `pegasus.catalog.replica.url` to specify the URL for the LRC to query. Details about RLS can be found at <http://www.globus.org/toolkit/data/rls/>

JDBCRC In this mode, Pegasus queries a SQL based replica catalog that is accessed via JDBC. The sql schema's for this catalog can be found at `$PEGASUS_HOME/sql` directory. To use JDBCRC, the user additionally needs to set the following properties

1. `pegasus.catalog.replica.db.driver = mysql`
2. `pegasus.catalog.replica.db.url = jdbc url to database e.g jdbc:mysql://database-host.isi.edu/database-name`
3. `pegasus.catalog.replica.db.user = database-user`
4. `pegasus.catalog.replica.db.password = database-password`

File In this mode, Pegasus queries a file based replica catalog. It is neither transactionally safe, nor advised to use for production purposes in any way. Multiple concurrent instances *will clobber* each other!. The site attribute should be specified whenever possible. The attribute key for the site attribute is "pool".

The LFN may or may not be quoted. If it contains linear whitespace, quotes, backslash or an equality sign, it must be quoted and escaped. Ditto for the PFN. The attribute key-value pairs are separated by an equality sign without any whitespaces. The value may be in quoted. The LFN sentiments about quoting apply.

```
LFN PFN
LFN PFN a=b [...]
LFN PFN a="b" [...]
"LFN w/LWS" "PFN w/LWS" [...]
```

To use File, the user additionally needs to specify `pegasus.catalog.replica.file` property to specify the path to the file based RC.

Regex In this mode, Pegasus queries a file based replica catalog. It is neither transactionally safe, nor advised to use for production purposes in any way. Multiple concurrent access to the File will end up clobbering the contents of the file. The site attribute should be specified whenever possible. The attribute key for the site attribute is "pool".

The LFN may or may not be quoted. If it contains linear whitespace, quotes, backslash or an equality sign, it must be quoted and escaped. Ditto for the PFN. The attribute key-value pairs are separated by an equality sign without any whitespaces. The value may be in quoted. The LFN sentiments about quoting apply.

In addition users can specify regular expression based LFN's. A regular expression based entry should be qualified with an attribute named 'regex'. The attribute `regex` when set to true identifies the catalog entry as a regular expression based entry. Regular expressions should follow Java regular expression syntax.

For example, consider a replica catalog as shown below.

Entry 1 refers to an entry which does not use a regular expressions. This entry would only match a file named 'f.a', and nothing else. Entry 2 refers to an entry which uses a regular expression. In this entry f.a refers to files having name as `f[any-character]a` i.e. faa, f.a, f0a, etc.

```
f.a file:///Volumes/data/input/f.a pool="local"
f.a file:///Volumes/data/input/f.a pool="local" regex="true"
```

Regular expression based entries also support substitutions. For example, consider the regular expression based entry shown below.

Entry 3 will match files with name alpha.csv, alpha.txt, alpha.xml. In addition, values matched in the expression can be used to generate a PFN.

For the entry below if the file being looked up is alpha.csv, the PFN for the file would be generated as file:///Volumes/data/input/csv/alpha.csv. Similarly if the file being looked up was alpha.xml, the PFN for the file would be generated as file:///Volumes/data/input/xml/alpha.xml i.e. The section [0], [1] will be replaced. Section [0] refers to the entire string i.e. alpha.csv. Section [1] refers to a partial match in the input i.e. csv, or txt, or xml. Users can utilize as many sections as they wish.

```
alpha\.(csv|txt|xml) file:///Volumes/data/input/[1]/[0] pool="local" regex="true"
```

To use File, the user additionally needs to specify pegasus.catalog.replica.file property to specify the path to the file based RC.

Directory

In this mode, Pegasus does a directory listing on an input directory to create the LFN to PFN mappings. The directory listing is performed recursively, resulting in deep LFN mappings. For example, if an input directory \$input is specified with the following structure

```
$input
$input/f.1
$input/f.2
$input/D1
$input/D1/f.3
```

Pegasus will create the mappings the following LFN PFN mappings internally

```
f.1 file://$input/f.1 pool="local"
f.2 file://$input/f.2 pool="local"
D1/f.3 file://$input/D1/f.3 pool="local"
```

If you don't want the deep lfn's to be created then, you can set pegasus.catalog.replica.directory.flat.lfn to true. In that case, for the previous example, Pegasus will create the following LFN PFN mappings internally.

```
f.1 file://$input/f.1 pool="local"
f.2 file://$input/f.2 pool="local"
f.3 file://$input/D1/f.3 pool="local"
```

pegasus-plan has --input-dir option that can be used to specify an input directory.

Users can optionally specify additional properties to configure the behavior of this implementation.

pegasus.catalog.replica.directory.site to specify a site attribute other than local to associate with the mappings.

pegasus.catalog.replica.directory.url.prefix to associate a URL prefix for the PFN's constructed. If not specified, the URL defaults to file://

MRC

In this mode, Pegasus queries multiple replica catalogs to discover the file locations on the grid. To use it set

```
pegasus.catalog.replica MRC
```

Each associated replica catalog can be configured via properties as follows.

The user associates a variable name referred to as [value] for each of the catalogs, where [value] is any legal identifier (concretely [A-Za-z][_A-Za-z0-9]*) For each associated replica catalogs the user specifies the following properties.

```
pegasus.catalog.replica.mrc.[value]      specifies the type of replica catalog.
pegasus.catalog.replica.mrc.[value].key  specifies a property name key for a
particular catalog
```

For example, if a user wants to query two lrc's at the same time he/she can specify as follows

```
pegasus.catalog.replica.mrc.lrc1 LRC
pegasus.catalog.replica.mrc.lrc2.url rls://sukhna
pegasus.catalog.replica.mrc.lrc2 LRC
pegasus.catalog.replica.mrc.lrc2.url rls://smarty
```

In the above example, lrc1, lrc2 are any valid identifier names and url is the property key that needed to be specified.

pegasus.catalog.replica.url

System:	Pegasus
Since:	2.0
Type:	URI string
Default:	(no default)

When using the modern RLS replica catalog, the URI to the Replica catalog must be provided to Pegasus to enable it to look up filenames. There is no default.

pegasus.catalog.replica.chunk.size

System:	Pegasus, rc-client
Since:	2.0
Type:	Integer
Default:	1000

The rc-client takes in an input file containing the mappings upon which to work. This property determines, the number of lines that are read in at a time, and worked upon at together. This allows the various operations like insert, delete happen in bulk if the underlying replica implementation supports it.

pegasus.catalog.replica.lrc.ignore

System:	Replica Catalog - RLS
Since:	2.0
Type:	comma separated list of LRC urls
Default:	(no default)
See also:	pegasus.catalog.replica.lrc.restrict

Certain users may like to skip some LRCs while querying for the physical locations of a file. If some LRCs need to be skipped from those found in the rli then use this property. You can define either the full URL or partial domain names that need to be skipped. E.g. If a user wants rls://smarty.isi.edu and all LRCs on usc.edu to be skipped then the property will be set as `pegasus.rls.lrc.ignore=rls://smarty.isi.edu,usc.edu`

pegasus.catalog.replica.lrc.restrict

System:	Replica Catalog - RLS
Since:	1.3.9
Type:	comma separated list of LRC urls
Default:	(no default)
See also:	pegasus.catalog.replica.lrc.ignore

This property applies a tighter restriction on the results returned from the LRCs specified. Only those PFNs are returned that have a pool attribute associated with them. The property "pegasus.rc.lrc.ignore" has a higher priority than "pegasus.rc.lrc.restrict". For example, in case a LRC is specified in both properties, the LRC would be ignored (i.e. not queried at all instead of applying a tighter restriction on the results returned).

pegasus.catalog.replica.lrc.site.[site-name]

System:	Replica Catalog - RLS
Since:	2.3.0
Type:	LRC url
Default:	(no default)

This property allows for the LRC url to be associated with site handles. Usually, a pool attribute is required to be associated with the PFN for Pegasus to figure out the site on which PFN resides. However, in the case where an LRC is responsible for only a single site's mappings, Pegasus can safely associate LRC url with the site. This association can be used to determine the pool attribute for all mappings returned from the LRC, if the mapping does not have a pool attribute associated with it.

The site_name in the property should be replaced by the name of the site. For example

```
pegasus.catalog.replica.lrc.site.isi rls://lrc.isi.edu
```

tells Pegasus that all PFNs returned from LRC rls://lrc.isi.edu are associated with site isi.

The [site_name] should be the same as the site handle specified in the site catalog.

pegasus.catalog.replica.cache.asrc

System:	Pegasus
Since:	2.0
Type:	Boolean
Value[0]:	false
Value[1]:	true
Default:	false
See also:	pegasus.catalog.replica

This property determines whether to treat the cache file specified as a supplemental replica catalog or not. User can specify on the command line to pegasus-plan a comma separated list of cache files using the --cache option. By default, the LFN->PFN mappings contained in the cache file are treated as cache, i.e if an entry is found in a cache file the replica catalog is not queried. This results in only the entry specified in the cache file to be available for replica selection.

Setting this property to true, results in the cache files to be treated as supplemental replica catalogs. This results in the mappings found in the replica catalog (as specified by pegasus.catalog.replica) to be merged with the ones found in the cache files. Thus, mappings for a particular LFN found in both the cache and the replica catalog are available for replica selection.

Site Catalog

pegasus.catalog.site

System:	Site Catalog
Since:	2.0

Type:	enumeration
Value[0]:	XML4
Value[1]:	XML3
Default:	XML4

The site catalog file format is now automatically detected, so there should be no need to use the property anymore.

pegasus.catalog.site.file

System:	Site Catalog
Since:	2.0
Type:	file location string
Default:	\${pegasus.home.sysconfdir}/sites.xml
See also:	pegasus.catalog.site

Running things on the grid requires an extensive description of the capabilities of each compute cluster, commonly termed "site". This property describes the location of the file that contains such a site description. As the format is currently in flow, please refer to the userguide and Pegasus for details which format is expected.

Transformation Catalog

pegasus.catalog.transformation

System:	Transformation Catalog
Since:	2.0
Type:	enumeration
Value[0]:	Text
Value[1]:	File
Default:	Text
See also:	pegasus.catalog.transformation.file

Text In this mode, a multiline file based format is understood. The file is read and cached in memory. Any modifications, as adding or deleting, causes an update of the memory and hence to the file underneath. All queries are done against the memory representation.

The file sample.tc.text in the etc directory contains an example

Here is a sample textual format for transformation catalog containing one transformation on two sites

```
tr example::keg:1.0 {
#specify profiles that apply for all the sites for the transformation
#in each site entry the profile can be overridden
profile env "APP_HOME" "/tmp/karan"
profile env "JAVA_HOME" "/bin/app"
site isi {
profile env "me" "with"
profile condor "more" "test"
profile env "JAVA_HOME" "/bin/java.1.6"
pfn "/path/to/keg"
arch "x86"
os "linux"
osrelease "fc"
osversion "4"
type "INSTALLED"
site wind {
```

```

profile env "me" "with"
profile condor "more" "test"
pfn "/path/to/keg"
arch "x86"
os "linux"
osrelease "fc"
osversion "4"
type "STAGEABLE"

```

File THIS FORMAT IS DEPRECATED. WILL BE REMOVED IN COMING VERSIONS. USE pegasus-tc-converter to convert File format to Text Format. In this mode, a file format is understood. The file is read and cached in memory. Any modifications, as adding or deleting, causes an update of the memory and hence to the file underneath. All queries are done against the memory representation. The new TC file format uses 6 columns:

1. The resource ID is represented in the first column.
2. The logical transformation uses the colonized format ns::name:vs.
3. The path to the application on the system
4. The installation type is identified by one of the following keywords - all upper case: INSTALLED, STAGEABLE. If not specified, or **NULL** is used, the type defaults to INSTALLED.
5. The system is of the format ARCH::OS[:VER:GLIBC]. The following arch types are understood: "INTEL32", "INTEL64", "SPARCV7", "SPARCV9". The following os types are understood: "LINUX", "SUNOS", "AIX". If unset or **NULL**, defaults to INTEL32::LINUX.
6. Profiles are written in the format NS::KEY=VALUE,KEY2=VALUE;NS2::KEY3=VALUE3 Multiple key-values for same namespace are separated by a comma "," and multiple namespaces are separated by a semicolon ";". If any of your profile values contains a comma you must not use the namespace abbreviator.

pegasus.catalog.transformation.file

Systems:	Transformation Catalog
Type:	file location string
Default:	\${pegasus.home.sysconfdir}/tc.text \${pegasus.home.sysconfdir}/tc.data
See also:	pegasus.catalog.transformation

This property is used to set the path to the textual transformation catalogs of type File or Text. If the transformation catalog is of type Text then tc.text file is picked up from sysconfdir, else tc.data

Provenance Catalog

pegasus.catalog.provenance

System:	Provenance Tracking Catalog (PTC)
Since:	2.0
Type:	Java class name
Value[0]:	InvocationSchema
Value[1]:	NXDInvSchema
Default:	(no default)
See also:	pegasus.catalog.*.db.driver

This property denotes the schema that is being used to access a PTC. The PTC is usually not a standard installation. If you use a database backend, you most likely have a schema that supports PTCs. By default, no PTC will be used.

Currently only the InvocationSchema is available for storing the provenance tracking records. Beware, this can become a lot of data. The values are names of Java classes. If no absolute Java classname is given, "org.griphyn.vdl.dbschema." is prepended. Thus, by deriving from the DatabaseSchema API, and implementing the PTC interface, users can provide their own classes here.

Alternatively, if you use a native XML database like eXist, you can store data using the NXDInvSchema. This will avoid using any of the other database driver properties.

pegasus.catalog.provenance.refinement

System:	PASOA Provenance Store
Since:	2.0.1
Type:	Java class name
Value[0]:	Pasoa
Value[1]:	InMemory
Default:	InMemory
See also:	pegasus.catalog.*.db.driver

This property turns on the logging of the refinement process that happens inside Pegasus to the PASOA store. Not all actions are currently captured. It is still an experimental feature.

The PASOA store needs to run on localhost on port 8080 <https://localhost:8080/prserv-1.0>

Replica Selection Properties

pegasus.selector.replica

System:	Replica Selection
Since:	2.0
Type:	URI string
Default:	default
See also:	pegasus.replica.*.ignore.stagein.sites
See also:	pegasus.replica.*.prefer.stagein.sites

Each job in the DAX maybe associated with input LFN's denoting the files that are required for the job to run. To determine the physical replica (PFN) for a LFN, Pegasus queries the replica catalog to get all the PFN's (replicas) associated with a LFN. Pegasus then calls out to a replica selector to select a replica amongst the various replicas returned. This property determines the replica selector to use for selecting the replicas.

Default If a PFN that is a file URL (starting with file:///) and has a pool attribute matching to the site handle of the site where the compute is to be run is found, then that is returned. Else, a random PFN is selected amongst all the PFN's that have a pool attribute matching to the site handle of the site where a compute job is to be run. Else, a random pfn is selected amongst all the PFN's.

Restricted This replica selector, allows the user to specify good sites and bad sites for staging in data to a particular compute site. A good site for a compute site X, is a preferred site from which replicas should be staged to site X. If there are more than one good sites having a particular replica, then a random site is selected amongst these preferred sites.

A bad site for a compute site X, is a site from which replica's should not be staged. The reason of not accessing replica from a bad site can vary from the link being down, to the user not having permissions on that site's data.

The good | bad sites are specified by the properties

```
pegasus.replica.*.prefer.stagein.sites
pegasus.replica.*.ignore.stagein.sites
```

where the * in the property name denotes the name of the compute site. A * in the property key is taken to mean all sites.

The `pegasus.replica.*.prefer.stagein.sites` property takes precedence over `pegasus.replica.*.ignore.stagein.sites` property i.e. if for a site X, a site Y is specified both in the ignored and the preferred set, then site Y is taken to mean as only a preferred site for a site X.

Regex This replica selector allows the user allows the user to specific regex expressions that can be used to rank various PFN's returned from the Replica Catalog for a particular LFN. This replica selector selects the highest ranked PFN i.e the replica with the lowest rank value.

The regular expressions are assigned different rank, that determine the order in which the expressions are employed. The rank values for the regex can expressed in user properties using the property.

```
pegasus.selector.replica.regex.rank.[value] regex-expression
```

The value is an integer value that denotes the rank of an expression with a rank value of 1 being the highest rank.

Please note that before applying any regular expressions on the PFN's, the file URL's that dont match the preferred site are explicitly filtered out.

Local This replica selector prefers replicas from the local host and that start with a file: URL scheme. It is useful, when users want to stagin files to a remote site from your submit host using the Condor file transfer mechanism.

pegasus.selector.replica.*.ignore.stagein.sites

System:	Replica Selection
Type:	comma separated list of sites
Since:	2.0
Default:	no default
See also:	pegasus.selector.replica
See also:	pegasus.selector.replica.*.prefer.stagein.sites

A comma separated list of storage sites from which to never stage in data to a compute site. The property can apply to all or a single compute site, depending on how the * in the property name is expanded.

The * in the property name means all compute sites unless replaced by a site name.

For e.g setting `pegasus.selector.replica.*.ignore.stagein.sites` to `usc` means that ignore all replicas from site `usc` for staging in to any compute site. Setting `pegasus.replica.isi.ignore.stagein.sites` to `usc` means that ignore all replicas from site `usc` for staging in data to site `isi`.

pegasus.selector.replica.*.prefer.stagein.sites

System:	Replica Selection
Type:	comma separated list of sites
Since:	2.0
Default:	no default

See also:	pegasus.selector.replica
See also:	pegasus.selector.replica.*.ignore.stagein.sites

A comma separated list of preferred storage sites from which to stage in data to a compute site. The property can apply to all or a single compute site, depending on how the * in the property name is expanded.

The * in the property name means all compute sites unless replaced by a site name.

For e.g setting pegasus.selector.replica.*.prefer.stagein.sites to usc means that prefer all replicas from site usc for staging in to any compute site. Setting pegasus.selector.replica.isi.prefer.stagein.sites to usc means that prefer all replicas from site usc for staging in data to site isi.

pegasus.selector.replica.regex.rank.[value]

System:	Replica Selection
Type:	Regex Expression
Since:	2.3.0
Default:	no default
See also:	pegasus.selector.replica

Specifies the regex expressions to be applied on the PFNs returned for a particular LFN. Refer to

<http://java.sun.com/javase/6/docs/api/java/util/regex/Pattern.html>

on information of how to construct a regex expression.

The [value] in the property key is to be replaced by an int value that designates the rank value for the regex expression to be applied in the Regex replica selector.

The example below indicates preference for file URL's over URL's referring to gridftp server at example.isi.edu

```
pegasus.selector.replica.regex.rank.1 file:///.*
pegasus.selector.replica.regex.rank.2 gsiftp://example\.\isi\.\edu.*
```

Site Selection Properties

pegasus.selector.site

System:	Pegasus
Since:	2.0
Type:	enumeration
Value[0]:	Random
Value[1]:	RoundRobin
Value[2]:	NonJavaCallout
Value[3]:	Group
Value[4]:	Heft
Default:	Random
See also:	pegasus.selector.site.path
See also:	pegasus.selector.site.timeout
See also:	pegasus.selector.site.keep.tmp

See also:

|pegasus.selector.site.env.*

The site selection in Pegasus can be on basis of any of the following strategies.

Random	In this mode, the jobs will be randomly distributed among the sites that can execute them.
RoundRobin	In this mode, the jobs will be assigned in a round robin manner amongst the sites that can execute them. Since each site cannot execute everytype of job, the round robin scheduling is done per level on a sorted list. The sorting is on the basis of the number of jobs a particular site has been assigned in that level so far. If a job cannot be run on the first site in the queue (due to no matching entry in the transformation catalog for the transformation referred to by the job), it goes to the next one and so on. This implementation defaults to classic round robin in the case where all the jobs in the workflow can run on all the sites.
NonJavaCallout	In this mode, Pegasus will callout to an external site selector. In this mode a temporary file is prepared containing the job information that is passed to the site selector as an argument while invoking it. The path to the site selector is specified by setting the property <code>pegasus.site.selector.path</code> . The environment variables that need to be set to run the site selector can be specified using the properties with a <code>pegasus.site.selector.env.</code> prefix. The temporary file contains information about the job that needs to be scheduled. It contains key value pairs with each key value pair being on a new line and separated by a <code>=</code> .

The following pairs are currently generated for the site selector temporary file that is generated in the NonJavaCallout.

version	is the version of the site selector api, currently 2.0.
transformation	is the fully-qualified definition identifier for the transformation (TR) namespace::name:version.
derivation	is the fully qualified definition identifier for the derivation (DV), namespace::name:version.
job.level	is the job's depth in the tree of the workflow DAG.
job.id	is the job's ID, as used in the DAX file.
resource.id	is a pool handle, followed by whitespace, followed by a gridftp server. Typically, each gridftp server is enumerated once, so you may have multiple occurrences of the same site. There can be multiple occurrences of this key.
input.lfn	is an input LFN, optionally followed by a whitespace and file size. There can be multiple occurrences of this key, one for each input LFN required by the job.
wf.name	label of the dax, as found in the DAX's root element. wf.index is the DAX index, that is incremented for each partition in case of deferred planning.
wf.time	is the mtime of the workflow.
wf.manager	is the name of the workflow manager being used .e.g condor
vo.name	is the name of the virtual organization that is running this workflow. It is currently set to NONE

	vo.group	unused at present and is set to NONE.
Group	In this mode, a group of jobs will be assigned to the same site that can execute them. The use of the PEGASUS profile key group in the dax, associates a job with a particular group. The jobs that do not have the profile key associated with them, will be put in the default group. The jobs in the default group are handed over to the "Random" Site Selector for scheduling.	
Heft	<p>In this mode, a version of the HEFT processor scheduling algorithm is used to schedule jobs in the workflow to multiple grid sites. The implementation assumes default data communication costs when jobs are not scheduled on to the same site. Later on this may be made more configurable.</p> <p>The runtime for the jobs is specified in the transformation catalog by associating the pegasus profile key runtime with the entries.</p> <p>The number of processors in a site is picked up from the attribute idle-nodes associated with the vanilla jobmanager of the site in the site catalog.</p>	

pegasus.selector.site.path

System:	Site Selector
Since:	2.0
Type:	String

If one calls out to an external site selector using the NonJavaCallout mode, this refers to the path where the site selector is installed. In case other strategies are used it does not need to be set.

pegasus.site.selector.env.*

System:	Pegasus
Since:	1.2.3
Type:	String

The environment variables that need to be set while callout to the site selector. These are the variables that the user would set if running the site selector on the command line. The name of the environment variable is got by stripping the keys of the prefix "pegasus.site.selector.env." prefix from them. The value of the environment variable is the value of the property.

e.g pegasus.site.selector.path.LD_LIBRARY_PATH /globus/lib would lead to the site selector being called with the LD_LIBRARY_PATH set to /globus/lib.

pegasus.selector.site.timeout

System:	Site Selector
Since:	2.0
Type:	non negative integer
Default:	60

It sets the number of seconds Pegasus waits to hear back from an external site selector using the NonJavaCallout interface before timing out.

pegasus.selector.site.keep.tmp

System:	Pegasus
---------	---------

Since:	2.0
Type:	enumeration
Value[0]:	onerror
Value[1]:	always
Value[2]:	never
Default:	onerror

It determines whether Pegasus deletes the temporary input files that are generated in the temp directory or not. These temporary input files are passed as input to the external site selectors.

A temporary input file is created for each that needs to be scheduled.

Data Staging Configuration

pegasus.data.configuration

System:	Pegasus
Since:	4.0
Type:	enumeration
Value[0]:	sharedfs
Value[1]:	nonsharedfs
Value[2]:	condorio
Default:	sharedfs

This property sets up Pegasus to run in different environments.

sharedfs If this is set, Pegasus will be setup to execute jobs on the shared filesystem on the execution site. This assumes, that the head node of a cluster and the worker nodes share a filesystem. The staging site in this case is the same as the execution site. Pegasus adds a create dir job to the executable workflow that creates a workflow specific directory on the shared filesystem . The data transfer jobs in the executable workflow (stage_in_ , stage_inter_ , stage_out_) transfer the data to this directory. The compute jobs in the executable workflow are launched in the directory on the shared filesystem. Internally, if this is set the following properties are set.

```
pegasus.execute.*.filesystem.local    false
```

condorio If this is set, Pegasus will be setup to run jobs in a pure condor pool, with the nodes not sharing a filesystem. Data is staged to the compute nodes from the submit host using Condor File IO. The planner is automatically setup to use the submit host (site local) as the staging site. All the auxillary jobs added by the planner to the executable workflow (create dir, data stagein and stage-out, cleanup) jobs refer to the workflow specific directory on the local site. The data transfer jobs in the executable workflow (stage_in_ , stage_inter_ , stage_out_) transfer the data to this directory. When the compute jobs start, the input data for each job is shipped from the workflow specific directory on the submit host to compute/worker node using Condor file IO. The output data for each job is similarly shipped back to the submit host from the compute/worker node. This setup is particularly helpful when running workflows in the cloud environment where setting up a shared filesystem across the VM's may be tricky. On loading this property, internally the following properties are set

```
pegasus.transfer.sls.*.impl           Condor
pegasus.execute.*.filesystem.local    true
pegasus.gridstart                     PegasusLite
pegasus.transfer.worker.package       true
```

nonsharedfs If this is set, Pegasus will be setup to execute jobs on an execution site without relying on a shared filesystem between the head node and the worker nodes. You can specify staging site (using --staging-site option to pegasus-plan) to indicate the site to use as a central storage location for a workflow. The staging site is independant of the execution sites on which a workflow executes. All the auxillary jobs added by the planner to the executable workflow (create dir, data stagein and stage-out, cleanup) jobs refer to the workflow specific directory on the staging site. The data transfer jobs in the executable workflow (stage_in_ , stage_inter_ , stage_out_) transfer the data to this directory. When the compute jobs start, the input data for each job is shipped from the workflow specific directory on the submit host to compute/worker node using pegasus-transfer. The output data for each job is similarly shipped back to the submit host from the compute/worker node. The protocols supported are at this time SRM, GridFTP, iRods, S3. This setup is particularly helpful when running workflows on OSG where most of the execution sites don't have enough data storage. Only a few sites have large amounts of data storage exposed that can be used to place data during a workflow run. This setup is also helpful when running workflows in the cloud environment where setting up a shared filesystem across the VM's may be tricky. On loading this property, internally the following properties are set

```

pegasus.execute.*.filesystem.local    true
pegasus.gridstart                     PegasusLite
pegasus.transfer.worker.package       true

```

pegasus.transfer.bypass.input.staging

System:	Pegasus
Since:	4.3
Type:	Boolean
Default:	(no default)
See also:	pegasus.data.configuration

When executiing in a non shared filesystem setup i.e data configuration set to nonsharedfs or condorio, Pegasus always stages the input files through the staging site i.e the stage-in job stages in data from the input site to the staging site. The PegasusLite jobs that start up on the worker nodes, then pull the input data from the staging site for each job.

This property can be used to setup the PegasusLite jobs to pull input data directly from the input site without going through the staging server. This is based on the assumption that the worker nodes can access the input site. If users set this to true, they should be aware that the access to the input site is no longer throttled (as in case of stage in jobs). If large number of compute jobs start at the same time in a workflow, the input server will see a connection from each job.

Transfer Configuration Properties

pegasus.transfer.*.impl

System:	Pegasus
Type:	enumeration
Value[0]:	Transfer
Value[1]:	GUC
Default:	Transfer
See also:	pegasus.transfer.refiner
Since:	2.0

Each compute job usually has data products that are required to be staged in to the execution site, materialized data products staged out to a final resting place, or staged to another job running at a different site. This property determines the underlying grid transfer tool that is used to manage the transfers.

The * in the property name can be replaced to achieve finer grained control to dictate what type of transfer jobs need to be managed with which grid transfer tool.

Usually, the arguments with which the client is invoked can be specified by

- the property `pegasus.transfer.arguments`
- associating the PEGASUS profile key `transfer.arguments`

The table below illustrates all the possible variations of the property.

Property Name	Applies to
<code>pegasus.transfer.stagein.impl</code>	the stage in transfer jobs
<code>pegasus.transfer.stageout.impl</code>	the stage out transfer jobs
<code>pegasus.transfer.inter.impl</code>	the inter pool transfer jobs
<code>pegasus.transfer.setup.impl</code>	the setup transfer job
<code>pegasus.transfer.*.impl</code>	apply to types of transfer jobs

Note: Since version 2.2.0 the worker package is staged automatically during staging of executables to the remote site. This is achieved by adding a setup transfer job to the workflow. The setup transfer job by default uses GUC to stage the data. The implementation to use can be configured by setting the property

```
pegasus.transfer.setup.impl
```

property. However, if you have `pegasus.transfer.*.impl` set in your properties file, then you need to set `pegasus.transfer.setup.impl` to GUC

The various grid transfer tools that can be used to manage data transfers are explained below

Transfer This results in `pegasus-transfer` to be used for transferring of files. It is a python based wrapper around various transfer clients like `globus-url-copy`, `lcg-copy`, `wget`, `cp`, `ln`. `pegasus-transfer` looks at source and destination url and figures out automatically which underlying client to use. `pegasus-transfer` is distributed with the PEGASUS and can be found at `$PEGASUS_HOME/bin/pegasus-transfer`.

For remote sites, Pegasus constructs the default path to `pegasus-transfer` on the basis of `PEGASUS_HOME` env profile specified in the site catalog. To specify a different path to the `pegasus-transfer` client, users can add an entry into the transformation catalog with fully qualified logical name as `pegasus::pegasus-transfer`

GUC This refers to the new `guc` client that does multiple file transfers per invocation. The `globus-url-copy` client distributed with Globus 4.x is compatible with this mode.

pegasus.transfer.refiner

System:	Pegasus
Type:	enumeration
Value[0]:	Basic
Value[1]:	Cluster
Default:	Cluster
Since:	2.0
See also:	<code>pegasus.transfer.*.impl</code>

This property determines how the transfer nodes are added to the workflow. The various refiners differ in the how they link the various transfer jobs, and the number of transfer jobs that are created per compute jobs.

Basic This is a basic refinement strategy that adds a stage-in job per compute job and a stage-out per compute jobs. It is not recommended to use this, especially for large workflows where lots of stage-in jobs maybe created for a workflow. This is only recommended for experimental setups.

Cluster In this refinement strategy, clusters of stage-in and stageout jobs are created per level of the workflow. This workflow allows you to control the number of stagein and stageout jobs by associating pegasus profiles stagein.clusters and stageout.clusters with the jobs or in the site catalog for the staging sites.

pegasus.transfer.sls.*.impl

System:	Pegasus
Type:	enumeration
Value[0]:	Transfer
Value[1]:	Condor
Default:	Transfer
Since:	2.2.0
See also:	pegasus.data.configuration
See also:	pegasus.execute.*.filesystem.local

This property specifies the transfer tool to be used for Second Level Staging (SLS) of input and output data between the head node and worker node filesystems.

Currently, the * in the property name CANNOT be replaced to achieve finer grained control to dictate what type of SLS transfers need to be managed with which grid transfer tool.

The various grid transfer tools that can be used to manage SLS data transfers are explained below

Transfer This results in pegasus-transfer to be used for transferring of files. It is a python based wrapper around various transfer clients like globus-url-copy, lcg-copy, wget, cp, ln . pegasus-transfer looks at source and destination url and figures out automatically which underlying client to use. pegasus-transfer is distributed with the PEGASUS and can be found at \$PEGASUS_HOME/bin/pegasus-transfer.

For remote sites, Pegasus constructs the default path to pegasus-transfer on the basis of PEGASUS_HOME env profile specified in the site catalog. To specify a different path to the pegasus-transfer client , users can add an entry into the transformation catalog with fully qualified logical name as pegasus::pegasus-transfer

Condor This results in Condor file transfer mechanism to be used to transfer the input data files from the submit host directly to the worker node directories. This is used when running in pure Condor mode or in a Condor pool that does not have a shared filesystem between the nodes.

When setting the SLS transfers to Condor make sure that the following properties are also set

```
pegasus.gridstart          PegasusLite
pegasus.execute.*.filesystem.local true
```

Alternatively, you can set

```
pegasus.data.configuration condorio
```

in lieu of the above 3 properties.

Also make sure that pegasus.gridstart is not set.

Please refer to the section on "Condor Pool Without a Shared Filesystem" in the chapter on Planning and Submitting.

pegasus.transfer.arguments

System:	Pegasus
Since:	2.0

Type:	String
Default:	(no default)
See also:	pegasus.transfer.sls.arguments

This determines the extra arguments with which the transfer implementation is invoked. The transfer executable that is invoked is dependant upon the transfer mode that has been selected. The property can be overloaded by associated the pegasus profile key transfer.arguments either with the site in the site catalog or the corresponding transfer executable in the transformation catalog.

pegasus.transfer.sls.arguments

System:	Pegasus
Since:	2.4
Type:	String
Default:	(no default)
See also:	pegasus.transfer.arguments
See also:	pegasus.transfer.sls.*.impl

This determines the extra arguments with which the SLS transfer implementation is invoked. The transfer executable that is invoked is dependant upon the SLS transfer implementation that has been selected.

pegasus.transfer.stage.sls.file

System:	Pegasus
Since:	3.0
Type:	Boolean
Default:	(no default)
See also:	pegasus.gridstart
See also:	pegasus.execute.*.filesystem.local

For executing jobs on the local filesystem, Pegasus creates sls files for each compute jobs. These sls files list the files that need to be staged to the worker node and the output files that need to be pushed out from the worker node after completion of the job. By default, pegasus will stage these SLS files to the shared filesystem on the head node as part of first level data stagein jobs. However, in the case where there is no shared filesystem between head nodes and the worker nodes, the user can set this property to false. This will result in the sls files to be transferred using the Condor File Transfer from the submit host.

pegasus.transfer.worker.package

System:	Pegasus
Type:	boolean
Default:	false
Since:	3.0
See also:	pegasus.data.configuration

By default, Pegasus relies on the worker package to be installed in a directory accessible to the worker nodes on the remote sites . Pegasus uses the value of PEGASUS_HOME environment profile in the site catalog for the remote sites, to then construct paths to pegasus auxillary executables like kickstart, pegasus-transfer, seqexec etc.

If the Pegasus worker package is not installed on the remote sites users can set this property to true to get Pegasus to deploy worker package on the nodes.

In the case of sharedfs setup, the worker package is deployed on the shared scratch directory for the workflow, that is accessible to all the compute nodes of the remote sites.

When running in nonsharefs environments, the worker package is first brought to the submit directory and then transferred to the worker node filesystem using Condor file IO.

pegasus.transfer.links

System:	Pegasus
Type:	boolean
Default:	false
Since:	2.0
See also:	pegasus.transfer

If this is set, and the transfer implementation is set to Transfer i.e. using the transfer executable distributed with the PEGASUS. On setting this property, if Pegasus while fetching data from the Replica Catalog sees a pool attribute associated with the PFN that matches the execution pool on which the data has to be transferred to, Pegasus instead of the URL returned by the Replica Catalog replaces it with a file based URL. This is based on the assumption that if the pools match the filesystems are visible to the remote execution directory where input data resides. On seeing both the source and destination urls as file based URLs the transfer executable spawns a job that creates a symbolic link by calling `ln -s` on the remote pool.

pegasus.transfer.*.remote.sites

System:	Pegasus
Type:	comma separated list of sites
Default:	no default
Since:	2.0

By default Pegasus looks at the source and destination URL's for to determine whether the associated transfer job runs on the submit host or the head node of a remote site, with preference set to run a transfer job to run on submit host.

Pegasus will run transfer jobs on the remote sites

- if the file server for the compute site is a file server i.e url prefix `file://`
- symlink jobs need to be added that require the symlink transfer jobs to be run remotely.

This property can be used to change the default behaviour of Pegasus and force pegasus to run different types of transfer jobs for the sites specified on the remote site.

The table below illustrates all the possible variations of the property.

Property Name	Applies to
pegasus.transfer.stagein.remote.sites	the stage in transfer jobs
pegasus.transfer.stageout.remote.sites	the stage out transfer jobs
pegasus.transfer.inter.remote.sites	the inter pool transfer jobs
pegasus.transfer.*.remote.sites	apply to types of transfer jobs

In addition `*` can be specified as a property value, to designate that it applies to all sites.

pegasus.transfer.staging.delimiter

System:	Pegasus
---------	---------

Since:	2.0
Type:	String
Default:	:
See also:	pegasus.transformation.selector

Pegasus supports executable staging as part of the workflow. Currently staging of statically linked executables is supported only. An executable is normally staged to the work directory for the workflow/partition on the remote site. The basename of the staged executable is derived from the namespace,name and version of the transformation in the transformation catalog. This property sets the delimiter that is used for the construction of the name of the staged executable.

pegasus.transfer.disable.chmod.sites

System:	Pegasus
Since:	2.0
Type:	comma separated list of sites
Default:	no default

During staging of executables to remote sites, chmod jobs are added to the workflow. These jobs run on the remote sites and do a chmod on the staged executable. For some sites, this maynot be required. The permissions might be preserved, or there maybe an automatic mechanism that does it.

This property allows you to specify the list of sites, where you do not want the chmod jobs to be executed. For those sites, the chmod jobs are replaced by NoOP jobs. The NoOP jobs are executed by Condor, and instead will immediately have a terminate event written to the job log file and removed from the queue.

pegasus.transfer.setup.source.base.url

System:	Pegasus
Type:	URL
Default:	no default
Since:	2.3

This property specifies the base URL to the directory containing the Pegasus worker package builds. During Staging of Executable, the Pegasus Worker Package is also staged to the remote site. The worker packages are by default pulled from the http server at pegasus.isi.edu. This property can be used to override the location from where the worker package are staged. This maybe required if the remote computes sites don't allows files transfers from a http server.

Gridstart And Exitcode Properties

pegasus.gridstart

System:	Pegasus
Since:	2.0
Type:	enumeration
Value[0]:	Kickstart
Value[1]:	None
Value[2]:	PegasusLite
Default:	Kickstart

See also: `pegasus.execute.*.filesystem.local`

Jobs that are launched on the grid maybe wrapped in a wrapper executable/script that enables information about about the execution, resource consumption, and - most importantly - the exitcode of the remote application. At present, a job scheduled on a remote site is launched with a gridstart if site catalog has the corresponding gridlaunch attribute set and the job being launched is not MPI.

Users can explicitly decide what gridstart to use for a job, by associating the pegasus profile key named gridstart with the job.

Kickstart	In this mode, all the jobs are lauched via kickstart. The kickstart executable is a light-weight program which connects the stdin,stdout and stderr filehandles for PEGASUS jobs on the remote site. Kickstart is an executable distributed with PEGASUS that can generally be found at <code>\${pegasus.home.bin}/kickstart</code> .
None	In this mode, all the jobs are launched directly on the remote site. Each job's stdin,stdout and stderr are connected to condor commands in a manner to ensure that they are sent back to the submit host.
PegasusLite	In this mode, the compute jobs are wrapped by PegasusLite instances. PegasusLite instance is a bash script, that is launced on the compute node. It determins at runtime the directory a job needs to execute in, pulls in data from the staging site , launches the job, pushes out the data and cleans up the directory after execution.

pegasus.gridstart.kickstart.set.xbit

System:	Pegasus
Since:	2.4
Type:	Boolean
Default:	false
See also:	<code>pegasus.transfer.disable.chmod.sites</code>

Kickstart has an option to set the X bit on an executable before it launches it on the remote site. In case of staging of executables, by default chmod jobs are launched that set the x bit of the user executables staged to a remote site.

On setting this property to true, kickstart gridstart module adds a -X option to kickstart arguments. The -X arguments tells kickstart to set the x bit of the executable before launching it.

User should usually disable the chmod jobs by setting the property `pegasus.transfer.disable.chmod.sites` , if they set this property to true.

pegasus.gridstart.kickstart.stat

System:	Pegasus
Since:	2.1
Type:	Boolean
Default:	false
See also:	<code>pegasus.gridstart.generate.lof</code>

Kickstart has an option to stat the input files and the output files. The stat information is collected in the XML record generated by kickstart. Since stat is an expensive operation, it is not turned on by on. Set this property to true if you want to see stat information for the input files and output files of a job in it's kickstart output.

pegasus.gridstart.generate.lof

System:	Pegasus
---------	---------

Since:	2.1
Type:	Boolean
Default:	false
See also:	pegasus.gridstart.kickstart.stat

For the stat option for kickstart, we generate 2 lof (list of filenames) files for each job. One lof file containing the input lfn's for the job, and the other containing output lfn's for the job. In some cases, it maybe beneficial to have these lof files generated but not do the actual stat. This property allows you to generate the lof files without triggering the stat in kickstart invocations.

pegasus.gridstart.invoke.always

System:	Pegasus
Since:	2.0
Type:	Boolean
Default:	false
See also:	pegasus.gridstart.invoke.length

Condor has a limit in it, that restricts the length of arguments to an executable to 4K. To get around this limit, you can trigger Kickstart to be invoked with the -I option. In this case, an arguments file is prepared per job that is transferred to the remote end via the Condor file transfer mechanism. This way the arguments to the executable are not specified in the condor submit file for the job. This property specifies whether you want to use the invoke option always for all jobs, or want it to be triggered only when the argument string is determined to be greater than a certain limit.

pegasus.gridstart.invoke.length

System:	Pegasus
Since:	2.0
Type:	Long
Default:	4000
See also:	pegasus.gridstart.invoke.always

Gridstart is automatically invoked with the -I option, if it is determined that the length of the arguments to be specified is going to be greater than a certain limit. By default this limit is set to 4K. However, it can be overridden by specifying this property.

Interface To Condor And Condor Dagman

The Condor DAGMan facility is usually activate using the condor_submit_dag command. However, many shapes of workflows have the ability to either overburden the submit host, or overflow remote gatekeeper hosts. While DAGMan provides throttles, unfortunately these can only be supplied on the command-line. Thus, PEGASUS provides a versatile wrapper to invoke DAGMan, called pegasus-submit-dag. It can be configured from the command-line, from user- and system properties, and by defaults.

pegasus.condor.logs.symmlink

System:	Condor
Type:	Boolean
Default:	false
Since:	3.0

Starting 4.2.1 release, this property defaults to false. Prior to that it defaulted to true.

If this property is set to true, then Pegasus will have the Condor common log [dagname]-0.log in the submit file as a symlink to a location in /tmp . You want to set this to true when your workflow submit directory is on the shared filesystem . You don't want the common log to get written to a shared filesystem. If the user knows for sure that the workflow submit directory is not on the shared filesystem, then the value to this property should be false.

pegasus.condor.arguments.quote

System:	Condor
Type:	Boolean
Default:	true
Since:	2.0
Old Name:	pegasus.condor.arguments.quote

This property determines whether to apply the new Condor quoting rules for quoting the argument string. The new argument quoting rules appeared in Condor 6.7.xx series. We have verified it for 6.7.19 version. If you are using an old condor at the submit host, set this property to false.

pegasus.dagman.notify

System:	DAGman wrapper
Type:	Case-insensitive enumeration
Value[0]:	Complete
Value[1]:	Error
Value[2]:	Never
Default:	Never
Document:	http://www.cs.wisc.edu/condor/manual/v6.9/condor_submit_dag.html
Document:	http://www.cs.wisc.edu/condor/manual/v6.9/condor_submit.html

The pegasus.dagman.nofity property has been deprecated in favor of the Pegasus notification framework. Please see the reference manual for details on how to get workflow notifications. pegasus.dagman.nofity will be removed in the an upcoming version of Pegasus.

pegasus.dagman.verbose

System:	DAGman wrapper
Type:	Boolean
Value[0]:	false
Value[1]:	true
Default:	false
Document:	http://www.cs.wisc.edu/condor/manual/v6.9/condor_submit_dag.html

The pegasus-submit-dag wrapper processes properties to set DAGMan commandline arguments. If set and true, the argument activates verbose output in case of DAGMan errors.

pegasus.dagman.[category].maxjobs

System:	DAGman wrapper
Type:	Integer
Since:	2.2
Default:	no default
Document:	http://vtcpce.isi.edu/pegasus/index.php/ChangeLog/#Support_for_DAGMan_node_categories

DAGMan now allows for the nodes in the DAG to be grouped in category. The tuning parameters like maxjobs then can be applied per category instead of being applied to the whole workflow. To use this facility users need to associate the dagman profile key named category with their jobs. The value of the key is the category to which the job belongs to.

You can then use this property to specify the value for a category. For the above example you will set pegasus.dagman.short-running.maxjobs

Monitoring Properties

pegasus.monitord.events

System:	Pegasus-monitord
Type:	Boolean
Default:	true
Since:	3.0.2
See Also:	pegasus.monitord.output

This property determines whether pegasus-monitord generates log events. If log events are disabled using this property, no bp file, or database will be created, even if the pegasus.monitord.output property is specified.

pegasus.monitord.output

System:	Pegasus-monitord
Type:	String
Since:	3.0.2
See Also:	pegasus.monitord.events

This property specifies the destination for generated log events in pegasus-monitord. By default, events are stored in a sqlite database in the workflow directory, which will be created with the workflow's name, and a ".stampede.db" extension. Users can specify an alternative database by using a SQLAlchemy connection string. Details are available at:

<http://www.sqlalchemy.org/docs/05/reference/dialects/index.html>

It is important to note that users will need to have the appropriate db interface library installed. Which is to say, SQLAlchemy is a wrapper around the mysql interface library (for instance), it does not provide a MySQL driver itself. The Pegasus distribution includes both SQLAlchemy and the SQLite Python driver. As a final note, it is important to mention that unlike when using SQLite databases, using SQLAlchemy with other database servers, e.g. MySQL or Postgres, the target database needs to exist. Users can also specify a file name using this property in order to create a file with the log events.

Example values for the SQLAlchemy connection string for various end points are listed below

SQL Alchemy End Point	Example Value
-----------------------	---------------

Netlogger BP File	file:///submit/dir/myworkflow.bp
SQL Lite Database	sqlite:///submit/dir/myworkflow.db
MySQL Database	mysql://user:password@host:port/databasename

pegasus.dashboard.output

System:	Pegasus-monitor
Type:	String
Since:	4.2
See Also:	pegasus.monitor.output

This property specifies the destination for the workflow dashboard database. By default, the workflow dashboard database defaults to a sqlite database named workflow.db in the \$HOME/.pegasus directory. This database is shared for all workflows run as a particular user. Users can specify an alternative database by using a SQLAlchemy connection string. Details are available at:

<http://www.sqlalchemy.org/docs/05/reference/dialects/index.html>

It is important to note that users will need to have the appropriate db interface library installed. Which is to say, SQLAlchemy is a wrapper around the mysql interface library (for instance), it does not provide a MySQL driver itself. The Pegasus distribution includes both SQLAlchemy and the SQLite Python driver. As a final note, it is important to mention that unlike when using SQLite databases, using SQLAlchemy with other database servers, e.g. MySQL or Postgres, the target database needs to exist. Users can also specify a file name using this property in order to create a file with the log events.

Example values for the SQLAlchemy connection string for various end points are listed below

SQLAlchemy End Point	Example Value
SQL Lite Database	sqlite:///shared/myworkflow.db
MySQL Database	mysql://user:password@host:port/databasename

pegasus.monitor.notifications

System:	Pegasus-monitor
Type:	Boolean
Default:	true
Since:	3.1
See Also:	pegasus.monitor.notifications.max
See Also:	pegasus.monitor.notifications.timeout

This property determines whether pegasus-monitor processes notifications. When notifications are enabled, pegasus-monitor will parse the .notify file generated by pegasus-plan and will invoke notification scripts whenever conditions matches one of the notifications.

pegasus.monitor.notifications.max

System:	Pegasus-monitor
Type:	Integer
Default:	10
Since:	3.1

See Also:	pegasus.monitord.notifications
See Also:	pegasus.monitord.notifications.timeout

This property determines how many notification scripts pegasus-monitord will call concurrently. Upon reaching this limit, pegasus-monitord will wait for one notification script to finish before issuing another one. This is a way to keep the number of processes under control at the submit host. Setting this property to 0 will disable notifications completely.

pegasus.monitord.notifications.timeout

System:	Pegasus-monitord
Type:	Integer
Default:	0
Since:	3.1
See Also:	pegasus.monitord.notifications
See Also:	pegasus.monitord.notifications.max

This property determines how long will pegasus-monitord let notification scripts run before terminating them. When this property is set to 0 (default), pegasus-monitord will not terminate any notification scripts, letting them run indefinitely. If some notification scripts misbehave, this has the potential problem of starving pegasus-monitord's notification slots (see the pegasus.monitord.notifications.max property), and block further notifications. In addition, users should be aware that pegasus-monitord will not exit until all notification scripts are finished.

pegasus.monitord.stdout.disable.parsing

System:	Pegasus-monitord
Type:	Boolean
Default:	False
Since:	3.1.1

By default, pegasus-monitord parses the stdout/stderr section of the kickstart to populate the applications captured stdout and stderr in the job instance table for the stampede schema. For large workflows, this may slow down monitord especially if the application is generating a lot of output to its stdout and stderr. This property, can be used to turn off the database population.

Job Clustering Properties

pegasus.clusterer.job.aggregator

System:	Job Clustering
Since:	2.0
Type:	String
Value[0]:	seqexec
Value[1]:	mpiexec
Default:	seqexec

A large number of workflows executed through the Virtual Data System, are composed of several jobs that run for only a few seconds or so. The overhead of running any job on the grid is usually 60 seconds or more. Hence, it makes sense to collapse small independent jobs into a larger job. This property determines, the executable that will be used for running the larger job on the remote site.

seqexec	In this mode, the executable used to run the merged job is seqexec that runs each of the smaller jobs sequentially on the same node. The executable "seqexec" is a PEGASUS tool distributed in the PEGASUS worker package, and can be usually found at {pegasus.home}/bin/seqexec.
mpiexec	In this mode, the executable used to run the merged job is mpiexec that runs the smaller jobs via mpi on n nodes where n is the nodecount associated with the merged job. The executable "mpiexec" is a PEGASUS tool distributed in the PEGASUS worker package, and can be usually found at {pegasus.home}/bin/mpiexec.

pegasus.clusterer.job.aggregator.seqexec.log

System:	Job Clustering
Type:	Boolean
Default:	false
Since:	2.3
See also:	pegasus.clusterer.job.aggregator
See also:	pegasus.clusterer.job.aggregator.seqexec.log.global

Seqexec logs the progress of the jobs that are being run by it in a progress file on the remote cluster where it is executed.

This property sets the Boolean flag, that indicates whether to turn on the logging or not.

pegasus.clusterer.job.aggregator.seqexec.log.global

System:	Job Clustering
Type:	Boolean
Default:	true
Since:	2.3
See also:	pegasus.clusterer.job.aggregator
See also:	pegasus.clusterer.job.aggregator.seqexec.log
Old Name:	pegasus.clusterer.job.aggregator.seqexec.hasgloballog

Seqexec logs the progress of the jobs that are being run by it in a progress file on the remote cluster where it is executed. The progress log is useful for you to track the progress of your computations and remote grid debugging. The progress log file can be shared by multiple seqexec jobs that are running on a particular cluster as part of the same workflow. Or it can be per job.

This property sets the Boolean flag, that indicates whether to have a single global log for all the seqexec jobs on a particular cluster or progress log per job.

pegasus.clusterer.job.aggregator.seqexec.firstjobfail

System:	Job Clustering
Type:	Boolean
Default:	true
Since:	2.2
See also:	pegasus.clusterer.job.aggregator

By default seqexec does not stop execution even if one of the clustered jobs it is executing fails. This is because seqexec tries to get as much work done as possible.

This property sets the Boolean flag, that indicates whether to make seqexec stop on the first job failure it detects.

pegasus.clusterer.label.key

System:	Job Clustering
Type:	String
Default:	label
Since:	2.0
See also:	pegasus.partitioner.label.key

While clustering jobs in the workflow into larger jobs, you can optionally label your graph to control which jobs are clustered and to which clustered job they belong. This done using a label based clustering scheme and is done by associating a profile/label key in the PEGASUS namespace with the jobs in the DAX. Each job that has the same value/label value for this profile key, is put in the same clustered job.

This property allows you to specify the PEGASUS profile key that you want to use for label based clustering.

Logging Properties

pegasus.log.manager

System:	Pegasus
Since:	2.2.0
Type:	Enumeration
Value[0]:	Default
Value[1]:	Log4j
Default:	Default
See also:	pegasus.log.manager.formatter

This property sets the logging implementation to use for logging.

Default This implementation refers to the legacy Pegasus logger, that logs directly to stdout and stderr. It however, does have the concept of levels similar to log4j or syslog.

Log4j This implementation, uses Log4j to log messages. The log4j properties can be specified in a properties file, the location of which is specified by the property

```
pegasus.log.manager.log4j.conf
```

pegasus.log.manager.formatter

System:	Pegasus
Since:	2.2.0
Type:	Enumeration
Value[0]:	Simple
Value[1]:	Netlogger
Default:	Simple
See also:	pegasus.log.manager.formatter

This property sets the formatter to use for formatting the log messages while logging.

Simple This formats the messages in a simple format. The messages are logged as is with minimal formatting. Below are sample log messages in this format while ranking a dax according to performance.

```

event.pegasus.ranking dax.id sel8-gda.dax - STARTED
event.pegasus.parsing.dax dax.id sel8-gda-nested.dax - STARTED
event.pegasus.parsing.dax dax.id sel8-gda-nested.dax - FINISHED
job.id jobGDA
job.id jobGDA query.name getpredicted performace time 10.00
event.pegasus.ranking dax.id sel8-gda.dax - FINISHED

```

Netlogger This formats the messages in the Netlogger format , that is based on key value pairs. The netlogger format is useful for loading the logs into a database to do some meaningful analysis. Below are sample log messages in this format while ranking a dax according to performance.

```

ts=2008-09-06T12:26:20.100502Z event=event.pegasus.ranking.start \
msgid=6bc49c1f-112e-4cdb-af54-3e0afb5d593c \

```

pegasus.log.*

System:	Pegasus
Since:	2.0
Type:	String
Default:	No default

This property sets the path to the file where all the logging for Pegasus can be redirected to. Both stdout and stderr are logged to the file specified.

pegasus.log.metrics

System:	Pegasus
Since:	2.1.0
Type:	Boolean
Default:	true
See also:	pegasus.log.metrics.file

This property enables the logging of certain planning and workflow metrics to a global log file. By default the file to which the metrics are logged is `${pegasus.home}/var/pegasus.log`.

pegasus.log.metrics.file

System:	Pegasus
Since:	2.1.0

Type:	Boolean
Default:	<code>\${pegasus.home}/var/pegasus.log</code>
See also:	<code>pegasus.log.metrics</code>

This property determines the file to which the workflow and planning metrics are logged if enabled.

pegasus.metrics.app

System:	Pegasus
Since:	4.3.0
Type:	String
See also:	<code>pegasus.log.metrics</code>

This property namespace allows users to pass application level metrics to the metrics server. The value of this property is the name of the application.

Additional application specific attributes can be passed by using the prefix `pegasus.metrics.app`

```
pegasus.metrics.app.[attribute-name]      attribute-value
```

Note: the attribute cannot be named `name`. This attribute is automatically assigned the value from `pegasus.metrics.app`

Miscellaneous Properties

pegasus.code.generator

System:	Pegasus
Since:	3.0
Type:	enumeration
Value[0]:	Condor
Value[1]:	Shell
Value[2]:	PMC
Default:	Condor

This property is used to load the appropriate Code Generator to use for writing out the executable workflow.

- Condor This is the default code generator for Pegasus . This generator generates the executable workflow as a Condor DAG file and associated job submit files. The Condor DAG file is passed as input to Condor DAGMan for job execution.
- Shell This Code Generator generates the executable workflow as a shell script that can be executed on the submit host. While using this code generator, all the jobs should be mapped to site local i.e specify `--sites local` to `pegasus-plan`.
- PMC This Code Generator generates the executable workflow as a PMC task workflow. This is useful to run on platforms where it not feasible to run Condor such as the new XSEDE machines such as Blue Waters. In this mode, Pegasus will generate the executable workflow as a PMC task workflow and a sample PBS submit script that submits this workflow.

pegasus.register

System:	Pegasus
---------	---------

Since:	4.1.0
Type:	Boolean
Default:	true

Pegasus creates registration jobs to register the output files in the replica catalog. An output file is registered only if

- 1) a user has configured a replica catalog in the properties
- 2) the register flags for the output files in the DAX are set to true

This property can be used to turn off the creation of the registration jobs even though the files maybe marked to be registered in the replica catalog.

pegasus.job.priority.assign

System:	Pegasus
Since:	3.0.3
Type:	Boolean
Default:	true

This property can be used to turn off the default level based condor priorities that are assigned to jobs in the executable workflow.

pegasus.file.cleanup.strategy

System:	Pegasus
Since:	2.2
Type:	enumeration
Value[0]:	InPlace
Default:	InPlace

This property is used to select the strategy of how the the cleanup nodes are added to the executable workflow.

InPlace This is the only mode available .

pegasus.file.cleanup.impl

System:	Pegasus
Since:	2.2
Type:	enumeration
Value[0]:	Cleanup
Value[1]:	RM
Value[2]:	S3
Default:	Cleanup

This property is used to select the executable that is used to create the working directory on the compute sites.

Cleanup The default executable that is used to delete files is the dirmanager executable shipped with Pegasus. It is found at \$PEGASUS_HOME/bin/dirmanager in the pegasus distribution. An entry for transformation pegasus::dirmanager needs to exist in the Transformation Catalog or the PEGASUS_HOME environment variable should be specified in the site catalog for the sites for this mode to work.

RM This mode results in the rm executable to be used to delete files from remote directories. The rm executable is standard on *nix systems and is usually found at /bin/rm location.

- S3 This mode is used to delete files/objects from the buckets in S3 instead of a directory. This should be set when running workflows on Amazon EC2. This implementation relies on s3cmd command line client to create the bucket. An entry for transformation amazon::s3cmd needs to exist in the Transformation Catalog for this to work.

pegasus.file.cleanup.clusters.num

System:	Pegasus
Since:	4.2
Type:	Integer
Default:	2

In case of the InPlace strategy for adding the cleanup nodes to the workflow, this property specifies the maximum number of cleanup jobs that are added to the executable workflow on each level.

pegasus.file.cleanup.clusters.size

System:	Pegasus
Since:	4.2.1
Type:	Integer
Default:	2

In case of the InPlace strategy this property sets the number of cleanup jobs that get clustered into a bigger cleanup job. This parameters is only used if pegasus.file.cleanup.clusters.num is not set.

pegasus.file.cleanup.scope

System:	Pegasus
Since:	2.3.0
Type:	enumeration
Value[0]:	fullahead
Value[1]:	deferred
Default:	fullahead

By default in case of deferred planning InPlace file cleanup is turned OFF. This is because the cleanup algorithm does not work across partitions. This property can be used to turn on the cleanup in case of deferred planning.

- fullahead This is the default scope. The pegasus cleanup algorithm does not work across partitions in deferred planning. Hence the cleanup is always turned OFF, when deferred planning occurs and cleanup scope is set to full ahead.
- deferred If the scope is set to deferred, then Pegasus will not disable file cleanup in case of deferred planning. This is useful for scenarios where the partitions themselves are independant (i.e. dont share files). Even if the scope is set to deferred, users can turn off cleanup by specifying --nocleanup option to pegasus-plan.

pegasus.catalog.transformation.mapper

System:	Staging of Executables
Since:	2.0

Type:	enumeration
Value[0]:	All
Value[1]:	Installed
Value[2]:	Staged
Value[3]:	Submit
Default:	All
See also:	pegasus.transformation.selector

Pegasus now supports transfer of statically linked executables as part of the concrete workflow. At present, there is only support for staging of executables referred to by the compute jobs specified in the DAX file. Pegasus determines the source locations of the binaries from the transformation catalog, where it searches for entries of type `STATIC_BINARY` for a particular architecture type. The PFN for these entries should refer to a globus-url-copy valid and accessible remote URL. For transfer of executables, Pegasus constructs a soft state map that resides on top of the transformation catalog, that helps in determining the locations from where an executable can be staged to the remote site.

This property determines, how that map is created.

All	In this mode, all sources with entries of type <code>STATIC_BINARY</code> for a particular transformation are considered valid sources for the transfer of executables. This the most general mode, and results in the constructing the map as a result of the cartesian product of the matches.
Installed	In this mode, only entries that are of type <code>INSTALLED</code> are used while constructing the soft state map. This results in Pegasus never doing any transfer of executables as part of the workflow. It always prefers the installed executables at the remote sites.
Staged	In this mode, only entries that are of type <code>STATIC_BINARY</code> are used while constructing the soft state map. This results in the concrete workflow referring only to the staged executables, irrespective of the fact that the executables are already installed at the remote end.
Submit	In this mode, only entries that are of type <code>STATIC_BINARY</code> and reside at the submit host (pool local), are used while constructing the soft state map. This is especially helpful, when the user wants to use the latest compute code for his computations on the grid and that relies on his submit host.

pegasus.selector.transformation

System:	Staging of Executables
Since:	2.0
Type:	enumeration
Value[0]:	Random
Value[1]:	Installed
Value[2]:	Staged
Value[3]:	Submit
Default:	Random
See also:	pegasus.catalog.transformation

In case of transfer of executables, Pegasus could have various transformations to select from when it schedules to run a particular compute job at a remote site. For e.g it can have the choice of staging an executable from a particular remote pool, from the local (submit host) only, use the one that is installed on the remote site only.

This property determines, how a transformation amongst the various candidate transformations is selected, and is applied after the property `pegasus.tc` has been applied. For e.g specifying `pegasus.tc` as `Staged` and then `pegasus.transformation.selector` as `INSTALLED` does not work, as by the time this property is applied, the soft state map only has entries of type `STAGED`.

Random	In this mode, a random matching candidate transformation is selected to be staged to the remote execution pool.
Installed	In this mode, only entries that are of type INSTALLED are selected. This means that the concrete workflow only refers to the transformations already pre installed on the remote pools.
Staged	In this mode, only entries that are of type STATIC_BINARY are selected, ignoring the ones that are installed at the remote site.
Submit	In this mode, only entries that are of type STATIC_BINARY and reside at the submit host (pool local), are selected as sources for staging the executables to the remote execution pools.

pegasus.execute.*.filesystem.local

System:	Pegasus
Type:	Boolean
Default:	false
Since:	2.1.0
See also:	pegasus.data.configuration

Normally, Pegasus transfers the data to and from a directory on the shared filesystem on the head node of a compute site. The directory needs to be visible to both the head node and the worker nodes for the compute jobs to execute correctly.

By setting this property to true, you can get Pegasus to execute jobs on the worker node filesystem. In this case, when the jobs are launched on the worker nodes, the jobs grab the input data from the workflow specific execution directory on the compute site and push the output data to the same directory after completion. The transfer of data to and from the worker node directory is referred to as Second Level Staging (SLS).

pegasus.parser.dax.preserver.linebreaks

System:	Pegasus
Type:	Boolean
Default:	false
Since:	2.2.0

The DAX Parser normally does not preserve line breaks while parsing the CDATA section that appears in the arguments section of the job element in the DAX. On setting this to true, the DAX Parser preserves any line line breaks that appear in the CDATA section.

Profiles

The Pegasus Workflow Mapper uses the concept of profiles to encapsulate configurations for various aspects of dealing with the Grid infrastructure. Profiles provide an abstract yet uniform interface to specify configuration options for various layers from planner/mapper behavior to remote environment settings. At various stages during the mapping process, profiles may be added associated with the job.

This document describes various types of profiles, levels of priorities for intersecting profiles, and how to specify profiles in different contexts.

Profile Structure Heading

All profiles are triples comprised of a namespace, a name or key, and a value. The namespace is a simple identifier. The key has only meaning within its namespace, and it's yet another identifier. There are no constraints on the contents of a value

Profiles may be represented with different syntaxes in different context. However, each syntax will describe the underlying triple.

Profile Namespaces

Each namespace refers to a different aspect of a job's runtime settings. A profile's representation in the concrete plan (e.g. the Condor submit files) depends its namespace. Pegasus supports the following Namespaces for profiles:

- **env** permits remote environment variables to be set.
- **globus** sets Globus RSL parameters.
- **condor** sets Condor configuration parameters for the submit file.
- **dagman** introduces Condor DAGMan configuration parameters.
- **pegasus** configures the behaviour of various planner/mapper components.

The env Profile Namespace

The *env* namespace allows users to specify environment variables of remote jobs. Globus transports the environment variables, and ensure that they are set before the job starts.

The key used in conjunction with an *env* profile denotes the name of the environment variable. The value of the profile becomes the value of the remote environment variable.

Grid jobs usually only set a minimum of environment variables by virtue of Globus. You cannot compare the environment variables visible from an interactive login with those visible to a grid job. Thus, it often becomes necessary to set environment variables like LD_LIBRARY_PATH for remote jobs.

If you use any of the Pegasus worker package tools like transfer or the rc-client, it becomes necessary to set PEGASUS_HOME and GLOBUS_LOCATION even for jobs that run locally

Table 10.1. Table 1: Useful Environment Settings

Environment Variable	Description
PEGASUS_HOME	Used by auxillary jobs created by Pegasus both on remote site and local site. Should be set usually set in the Site Catalog for the sites
GLOBUS_LOCATION	Used by auxillary jobs created by Pegasus both on remote site and local site. Should be set usually set in the Site Catalog for the sites
LD_LIBRARY_PATH	Point this to \$GLOBUS_LOCATION/lib, except you cannot use the dollar variable. You must use the full path. Applies to both, local and remote jobs that use Globus components and should be usually set in the site catalog for the sites

Even though Condor and Globus both permit environment variable settings through their profiles, all remote environment variables must be set through the means of *env* profiles.

The Globus Profile Namespace

The *globus* profile namespace encapsulates Globus resource specification language (RSL) instructions. The RSL configures settings and behavior of the remote scheduling system. Some systems require queue name to schedule jobs, a project name for accounting purposes, or a run-time estimate to schedule jobs. The Globus RSL addresses all these issues.

A key in the *globus* namespace denotes the command name of an RLS instruction. The profile value becomes the RSL value. Even though Globus RSL is typically shown using parentheses around the instruction, the out pair of parentheses is not necessary in globus profile specifications

Table 2 shows some commonly used RSL instructions. For an authoritative list of all possible RSL instructions refer to the Globus RSL specification.

Table 10.2. Table 2: Useful Globus RSL Instructions

Key	Description
count	the number of times an executable is started.
jobtype	specifies how the job manager should start the remote job. While Pegasus defaults to single, use mpi when running MPI jobs.
maxcputime	the max cpu time for a single execution of a job.
maxmemory	the maximum memory in MB required for the job
maxtime	the maximum time or walltime for a single execution of a job.
maxwalltime	the maximum walltime for a single execution of a job.
minmemory	the minumum amount of memory required for this job
project	associates an account with a job at the remote end.
queue	the remote queue in which the job should be run. Used when remote scheduler is PBS that supports queues.

Pegasus prevents the user from specifying certain RSL instructions as globus profiles, because they are either automatically generated or can be overridden through some different means. For instance, if you need to specify remote environment settings, do not use the environment key in the globus profiles. Use one or more env profiles instead.

Table 10.3. Table 3: RSL Instructions that are not permissible

Key	Reason for Prohibition
arguments	you specify arguments in the arguments section for a job in the DAX
directory	the site catalog and properties determine which directory a job will run in.
environment	use multiple env profiles instead
executable	the physical executable to be used is specified in the transformation catalog and is also dependant on the gridstart module being used. If you are launching jobs via kickstart then the executable created is the path to kickstart and the application executable path appears in the arguments for kickstart
stdin	you specify in the DAX for the job
stdout	you specify in the DAX for the job
stderr	you specify in the DAX for the job

The Condor Profile Namespace

The Condor submit file controls every detail how and where a job is run. The *condor* profiles permit to add or overwrite instructions in the Condor submit file.

The *condor* namespace directly sets commands in the Condor submit file for a job the profile applies to. Keys in the *condor* profile namespace denote the name of the Condor command. The profile value becomes the command's argument. All *condor* profiles are translated into key=value lines in the Condor submit file

Some of the common condor commands that a user may need to specify are listed below. For an authoritative list refer to the online condor documentation. Note: Pegasus Workflow Planner/Mapper by default specify a lot of condor commands in the submit files depending upon the job, and where it is being run.

Table 10.4. Table 4: Useful Condor Commands

Key	Description
universe	Pegasus defaults to either globus or scheduler universes. Set to standard for compute jobs that require standard universe. Set to vanilla to run natively in a condor pool, or to run on resources grabbed via condor glidein.
periodic_release	is the number of times job is released back to the queue if it goes to HOLD, e.g. due to Globus errors. Pegasus defaults to 3.
periodic_remove	is the number of times a job is allowed to get into HOLD state before being removed from the queue. Pegasus defaults to 3.
filesystemdomain	Useful for Condor glide-ins to pin a job to a remote site.
stream_error	boolean to turn on the streaming of the stderr of the remote job back to submit host.
stream_output	boolean to turn on the streaming of the stdout of the remote job back to submit host.
priority	integer value to assign the priority of a job. Higher value means higher priority. The priorities are only applied for vanilla / standard/ local universe jobs. Determines the order in which a users own jobs are executed.
request_cpus	New in Condor 7.8.0 . Number of CPU's a job requires.
request_memory	New in Condor 7.8.0 . Amount of memory a job requires.
request_disk	New in Condor 7.8.0 . Amount of disk a job requires.

Other useful condor keys, that advanced users may find useful and can be set by profiles are

1. should_transfer_files
2. transfer_output
3. transfer_error
4. whentotransferoutput
5. requirements
6. rank

Pegasus prevents the user from specifying certain Condor commands in condor profiles, because they are automatically generated or can be overridden through some different means. Table 5 shows prohibited Condor commands.

Table 10.5. Table 5: Condor commands prohibited in condor profiles

Key	Reason for Prohibition
arguments	you specify arguments in the arguments section for a job in the DAX
environment	use multiple env profiles instead
executable	the physical executable to be used is specified in the transformation catalog and is also dependant on the gridstart

module being used. If you are launching jobs via kickstart then the executable created is the path to kickstart and the application executable path appears in the arguments for kickstart
--

The Dagman Profile Namespace

DAGMan is Condor's workflow manager. While planners generate most of DAGMan's configuration, it is possible to tweak certain job-related characteristics using dagman profiles. A dagman profile can be used to specify a DAGMan pre- or post-script.

Pre- and post-scripts execute on the submit machine. Both inherit the environment settings from the submit host when pegasus-submit-dag or pegasus-run is invoked.

By default, kickstart launches all jobs except standard universe and MPI jobs. Kickstart tracks the execution of the job, and returns usage statistics for the job. A DAGMan post-script starts the Pegasus application exitcode to determine, if the job succeeded. DAGMan receives the success indication as exit status from exitcode.

If you need to run your own post-script, you have to take over the job success parsing. The planner is set up to pass the file name of the remote job's stdout, usually the output from kickstart, as sole argument to the post-script.

Table 6 shows the keys in the dagman profile domain that are understood by Pegasus and can be associated at a per job basis.

Table 10.6. Table 6: Useful dagman Commands that can be associated at a per job basis

Key	Description
PRE	is the path to the pre-script. DAGMan executes the pre-script before it runs the job.
PRE.ARGUMENTS	are command-line arguments for the pre-script, if any.
POST	<p>is the postscript type/mode that a user wants to associate with a job.</p> <ol style="list-style-type: none"> 1. pegasus-exitcode - pegasus will by default associate this postscript with all jobs launched via kickstart, as long the POST.SCOPE value is not set to NONE. 2. none -means that no postscript is generated for the jobs. This is useful for MPI jobs that are not launched via kickstart currently. 3. any legal identifier - Any other identifier of the form ([_A-Za-z][_A-Za-z0-9]*), than one of the 2 reserved keywords above, signifies a user postscript. This allows the user to specify their own postscript for the jobs in the workflow. The path to the postscript can be specified by the dagman profile POST.PATH.[value] where [value] is this legal identifier specified. The user postscript is passed the name of the .out file of the job as the last argument on the command line. <p>For e.g. if the following dagman profiles were associated with a job X</p> <ol style="list-style-type: none"> a. POST with value user_script /bin/user_postscript b. POST.PATH.user_script with value /path/to/user/script c. POST.ARGUMENTS with value -verbose

	<p>then the following postscript will be associated with the job X in the .dag file</p> <p>/path/to/user/script -verbose X.out where X.out contains the stdout of the job X</p>
POST.PATH.* (where * is replaced by the value of the POST Profile)	the path to the post script on the submit host.
POST.ARGUMENTS	are the command line arguments for the post script, if any.
RETRY	is the number of times DAGMan retries the full job cycle from pre-script through post-script, if failure was detected.
CATEGORY	the DAGMan category the job belongs to.
PRIORITY	the priority to apply to a job. DAGMan uses this to select what jobs to release when MAXJOBS is enforced for the DAG.

Table 7 shows the keys in the dagman profile domain that are understood by Pegasus and can be used to apply to the whole workflow. These are used to control DAGMan's behavior at the workflow level, and are recommended to be specified in the properties file.

Table 10.7. Table 7: Useful dagman Commands that can be specified in the properties file.

Key	Description
MAXPRE	sets the maximum number of PRE scripts within the DAG that may be running at one time
MAXPOST	sets the maximum number of PRE scripts within the DAG that may be running at one time
MAXJOBS	sets the maximum number of jobs within the DAG that will be submitted to Condor at one time.
MAXIDLE	sets the maximum number of idle jobs within the DAG that will be submitted to Condor at one time.
[CATEGORY-NAME].MAXJOBS	is the value of maxjobs for a particular category. Users can associate different categories to the jobs at a per job basis. However, the value of a dagman knob for a category can only be specified at a per workflow basis in the properties.
POST.SCOPE	<p>scope for the postscripts.</p> <ol style="list-style-type: none"> 1. If set to all , means each job in the workflow will have a postscript associated with it. 2. If set to none , means no job has postscript associated with it. None mode should be used if you are running vanilla / standard/ local universe jobs, as in those cases Condor traps the remote exitcode correctly. None scope is not recommended for grid universe jobs. 3. If set to essential, means only essential jobs have post scripts associated with them. At present the only non essential job is the replica registration job.

The Pegasus Profile Namespace

The *pegasus* profiles allow users to configure extra options to the Pegasus Workflow Planner that can be applied selectively to a job or a group of jobs. Site selectors may use a sub-set of *pegasus* profiles for their decision-making.

Table 8 shows some of the useful configuration option Pegasus understands.

Table 10.8. Table 8: Useful pegasus Profiles.

Key	Description
workdir	Sets the remote initial dir for a Condor-G job. Overrides the work directory algorithm that uses the site catalog and properties.
clusters.num	Please refer to the Pegasus Clustering Guide for detailed description. This option determines the total number of clusters per level. Jobs are evenly spread across clusters.
clusters.size	Please refer to the Pegasus Clustering Guide for detailed description. This profile determines the number of jobs in each cluster. The number of clusters depends on the total number of jobs on the level.
cores	The number of cores, associated with the job. This is solely used for accounting purposes in the database while generating statistics. It corresponds to the multiplier_factor in the job_instance table described here.
runtime	Please refer to the Pegasus Clustering Guide for detailed description. This profile specifies the expected runtime of a job.
clusters.maxruntime	Please refer to the Pegasus Clustering Guide for detailed description. This profile specifies the maximum runtime of a job.
job.aggregator	Indicates the clustering executable that is used to run the clustered job on the remote site.
gridstart	Determines the executable for launching a job. Possible values are Kickstart NoGridStart at the moment.
gridstart.path	Sets the path to the gridstart . This profile is best set in the Site Catalog.
gridstart.arguments	Sets the arguments with which GridStart is used to launch a job on the remote site.
stagein.clusters	This key determines the maximum number of <i>stage-in</i> jobs that are can executed locally or remotely per compute site per workflow. This is used to configure the <i>Bundle Transfer Refiner</i> , which is the Default Refiner used in Pegasus. This profile is best set in the Site Catalog or in the Properties file
stagein.local.clusters	This key provides finer grained control in determining the number of stage-in jobs that are executed locally and are responsible for staging data to a particular remote site. This profile is best set in the Site Catalog or in the Properties file
stagein.remote.clusters	This key provides finer grained control in determining the number of stage-in jobs that are executed remotely on the remote site and are responsible for staging data to it. This profile is best set in the Site Catalog or in the Properties file
stageout.clusters	This key determines the maximum number of <i>stage-out</i> jobs that are can executed locally or remotely per compute site per workflow. This is used to configure the <i>Bundle Transfer Refiner</i> , , which is the Default Refiner used in Pegasus.

stageout.local.clusters	This key provides finer grained control in determining the number of stage-out jobs that are executed locally and are responsible for staging data from a particular remote site. This profile is best set in the Site Catalog or in the Properties file
stageout.remote.clusters	This key provides finer grained control in determining the number of stage-out jobs that are executed remotely on the remote site and are responsible for staging data from it. This profile is best set in the Site Catalog or in the Properties file
group	Tags a job with an arbitrary group identifier. The group site selector makes use of the tag.
change.dir	If true, tells <i>kickstart</i> to change into the remote working directory. Kickstart itself is executed in whichever directory the remote scheduling system chose for the job.
create.dir	If true, tells <i>kickstart</i> to create the the remote working directory before changing into the remote working directory. Kickstart itself is executed in whichever directory the remote scheduling system chose for the job.
transfer.proxy	If true, tells Pegasus to explicitly transfer the proxy for transfer jobs to the remote site. This is useful, when you want to use a full proxy at the remote end, instead of the limited proxy that is transferred by CondorG.
transfer.arguments	Allows the user to specify the arguments with which the transfer executable is invoked. However certain options are always generated for the transfer executable(base-uri se-mount-point).
style	Sets the condor submit file style. If set to globus, submit file generated refers to CondorG job submissions. If set to condor, submit file generated refers to direct Condor submission to the local Condor pool. It applies for glidein, where nodes from remote grid sites are glided into the local condor pool. The default style that is applied is globus.
pmc_request_memory	This key is used to set the -m option for pegasus-mpi-cluster. It specifies the amount of memory in MB that a job requires. This profile is usually set in the DAX for each job.
pmc_request_cpus	This key is used to set the -c option for pegasus-mpi-cluster. It specifies the number of cpu's that a job requires. This profile is usually set in the DAX for each job.
pmc_priority	This key is used to set the -p option for pegasus-mpi-cluster. It specifies the priority for a job . This profile is usually set in the DAX for each job. Negative values are allowed for priorities.
pmc_task_arguments	The key is used to pass any extra arguments to the PMC task during the planning time. They are added to the very end of the argument string constructed for the task in the PMC file. Hence, allows for overriding of any argument constructed by the planner for any particular task in the PMC job.

Sources for Profiles

Profiles may enter the job-processing stream at various stages. Depending on the requirements and scope a profile is to apply, profiles can be associated at

- as user property settings.
- dax level
- in the site catalog
- in the transformation catalog

Unfortunately, a different syntax applies to each level and context. This section shows the different profile sources and syntaxes. However, at the foundation of each profile lies the triple of namespace, key and value.

User Profiles in Properties

Users can specify all profiles in the properties files where the property name is **[namespace].key** and **value** of the property is the value of the profile.

Namespace can be env|condor|globus|dagman|pegasus

Any profile specified as a property applies to the whole workflow unless overridden at the DAX level , Site Catalog , Transformation Catalog Level.

Some profiles that they can be set in the properties file are listed below

```
env.JAVA_HOME "/software/bin/java"

condor.periodic_release 5
condor.periodic_remove my_own_expression
condor.stream_error true
condor.stream_output fa

globus.maxwalltime 1000
globus.maxtime 900
globus.maxcputime 10
globus.project test_project
globus.queue main_queue

dagman.post.arguments --test arguments
dagman.retry 4
dagman.post.simple_exitcode
dagman.post.path.simple_exitcode /bin/exitcode/exitcode.sh
dagman.post.scope all
dagman.maxpre 12

```

Profiles in DAX

The user can associate profiles with logical transformations in DAX. Environment settings required by a job's application, or a maximum estimate on the run-time are examples for profiles at this stage.

```
<job id="ID000001" namespace="asdf" name="preprocess" version="1.0"
  level="3" dv-namespace="voeckler" dv-name="top" dv-version="1.0">
  <argument>-a top -T10 -i <filename file="voeckler.f.a"/>
  -o <filename file="voeckler.f.b1"/>
  <filename file="voeckler.f.b2"/></argument>
  <profile namespace="pegasus" key="walltime">2</profile>
  <profile namespace="pegasus" key="diskspace">1</profile>
  &ml;
</job>
```

Profiles in Site Catalog

If it becomes necessary to limit the scope of a profile to a single site, these profiles should go into the site catalog. A profile in the site catalog applies to all jobs and all application run at the site. Commonly, site catalog profiles set environment settings like the LD_LIBRARY_PATH, or globus rsl parameters like queue and project names.

Currently, there is no tool to manipulate the site catalog, e.g. by adding profiles. Modifying the site catalog requires that you load it into your editor.

The XML version of the site catalog uses the following syntax:

```
<profile namespace="namespace" key="key">value</profile>
```

The XML schema requires that profiles are the first children of a pool element. If the element ordering is wrong, the XML parser will produce errors and warnings:

```
<pool handle="isi_condor" gridlaunch="/home/shared/pegasus/bin/kickstart">
  <profile namespace="env"
    key="GLOBUS_LOCATION">/home/shared/globus</profile>
  <profile namespace="env"
    key="LD_LIBRARY_PATH" >/home/shared/globus/lib</profile>
  <lrc url="rls://sukhna.isi.edu" />
  &mldr;
</pool>
```

The multi-line textual version of the site catalog uses the following syntax:

```
profile namespace "key" "value"
```

The order within the textual pool definition is not important. Profiles can appear anywhere:

```
pool isi_condor {
  gridlaunch "/home/shared/pegasus/bin/kickstart"
  profile env "GLOBUS_LOCATION" "/home/shared/globus"
  profile env "LD_LIBRARY_PATH" "/home/shared/globus/lib"
  &mldr;
}
```

Profiles in Transformation Catalog

Some profiles require a narrower scope than the site catalog offers. Some profiles only apply to certain applications on certain sites, or change with each application and site. Transformation-specific and CPU-specific environment variables, or job clustering profiles are good candidates. Such profiles are best specified in the transformation catalog.

Profiles associate with a physical transformation and site in the transformation catalog. The Database version of the transformation catalog also permits the convenience of connecting a transformation with a profile.

The Pegasus tc-client tool is a convenient helper to associate profiles with transformation catalog entries. As benefit, the user does not have to worry about formats of profiles in the various transformation catalog instances.

```
tc-client -a -P -E -p /home/shared/executables/analyze -t INSTALLED -r isi_condor -e
env::GLOBUS_LOCATION=&rdquor;/home/shared/globus&rdquor;
```

The above example adds an environment variable GLOBUS_LOCATION to the application /home/shared/executables/analyze on site isi_condor. The transformation catalog guide has more details on the usage of the tc-client.

Profiles Conflict Resolution

Irrespective of where the profiles are specified, eventually the profiles are associated with jobs. Multiple sources may specify the same profile for the same job. For instance, DAX may specify an environment variable X. The site catalog may also specify an environment variable X for the chosen site. The transformation catalog may specify an environment variable X for the chosen site and application. When the job is concretized, these three conflicts need to be resolved.

Pegasus defines a priority ordering of profiles. The higher priority takes precedence (overwrites) a profile of a lower priority.

1. Transformation Catalog Profiles
2. Site Catalog Profiles
3. DAX Profiles

4. Profiles in Properties

Details of Profile Handling

The previous sections omitted some of the finer details for the sake of clarity. To understand some of the constraints that Pegasus imposes, it is required to look at the way profiles affect jobs.

Details of env Profiles

Profiles in the env namespace are translated to a semicolon-separated list of key-value pairs. The list becomes the argument for the Condor environment command in the job's submit file.

```
#####
# Pegasus WMS SUBMIT FILE GENERATOR
# DAG : black-diamond, Index = 0, Count = 1
# SUBMIT FILE NAME : findrange_ID000002.sub
#####
globusrs1 = (jobtype=single)
environment=GLOBUS_LOCATION=/shared/globus;LD_LIBRARY_PATH=/shared/globus/lib;
executable = /shared/software/linux/pegasus/default/bin/kickstart
globusscheduler = columbus.isi.edu/jobmanager-condor
remote_initialdir = /shared/CONDOR/workdir/isi_hourglass
universe = globus
&mldr;
queue
#####
# END OF SUBMIT FILE
```

Condor-G, in turn, will translate the *environment* command for any remote job into Globus RSL environment settings, and append them to any existing RSL syntax it generates. To permit proper mixing, all *environment* setting should solely use the env profiles, and none of the Condor nor Globus environment settings.

If *kickstart* starts a job, it may make use of environment variables in its executable and arguments setting.

Details of globus Profiles

Profiles in the *globus* Namespaces are translated into a list of paranthesis-enclosed equal-separated key-value pairs. The list becomes the value for the Condor *globusrs1* setting in the job's submit file:

```
#####
# Pegasus WMS SUBMIT FILE GENERATOR
# DAG : black-diamond, Index = 0, Count = 1
# SUBMIT FILE NAME : findrange_ID000002.sub
#####
globusrs1 = (jobtype=single)(queue=fast)(project=nvo)
executable = /shared/software/linux/pegasus/default/bin/kickstart
globusscheduler = columbus.isi.edu/jobmanager-condor
remote_initialdir = /shared/CONDOR/workdir/isi_hourglass
universe = globus
&mldr;
queue
#####
# END OF SUBMIT FILE
```

For this reason, Pegasus prohibits the use of the *globusrs1* key in the *condor* profile namespace.

Replica Selection

Each job in the DAX may be associated with input LFN's denoting the files that are required for the job to run. To determine the physical replica (PFN) for a LFN, Pegasus queries the Replica catalog to get all the PFN's (replicas) associated with a LFN. The Replica Catalog may return multiple PFN's for each of the LFN's queried. Hence, Pegasus needs to select a single PFN amongst the various PFN's returned for each LFN. This process is known as replica selection in Pegasus. Users can specify the replica selector to use in the properties file.

This document describes the various Replica Selection Strategies in Pegasus.

Configuration

The user properties determine what replica selector Pegasus Workflow Mapper uses. The property **pegasus.selector.replica** is used to specify the replica selection strategy. Currently supported Replica Selection strategies are

1. Default
2. Restricted
3. Regex

The values are case sensitive. For example the following property setting will throw a Factory Exception .

```
pegasus.selector.replica default
```

The correct way to specify is

```
pegasus.selector.replica Default
```

Supported Replica Selectors

The various Replica Selectors supported in Pegasus Workflow Mapper are explained below

Default

This is the default replica selector used in the Pegasus Workflow Mapper. If the property `pegasus.selector.replica` is not defined in properties, then Pegasus uses this selector.

This selector looks at each PFN returned for a LFN and checks to see if

1. the PFN is a file URL (starting with file:///)
2. the PFN has a pool attribute matching to the site handle of the site where the compute job that requires the input file is to be run.

If a PFN matching the conditions above exists then that is returned by the selector .

Else, a random PFN is selected amongst all the PFN's that have a pool attribute matching to the site handle of the site where a compute job is to be run.

Else, a random pfn is selected amongst all the PFN's

To use this replica selector set the following property

```
pegasus.selector.replica Default
```

Restricted

This replica selector, allows the user to specify good sites and bad sites for staging in data to a particular compute site. A good site for a compute site X, is a preferred site from which replicas should be staged to site X. If there are more than one good sites having a particular replica, then a random site is selected amongst these preferred sites.

A bad site for a compute site X, is a site from which replica's should not be staged. The reason of not accessing replica from a bad site can vary from the link being down, to the user not having permissions on that site's data.

The good | bad sites are specified by the following properties

```
pegasus.replica.*.prefer.stagein.sites
pegasus.replica.*.ignore.stagein.sites
```

where the * in the property name denotes the name of the compute site. A * in the property key is taken to mean all sites. The value to these properties is a comma separated list of sites.

For example the following settings

```
pegasus.selector.replica.*.prefer.stagein.sites      usc
pegasus.replica.uwm.prefer.stagein.sites             isi,cit
```

means that prefer all replicas from site usc for staging in to any compute site. However, for uwm use a tighter constraint and prefer only replicas from site isi or cit. The pool attribute associated with the PFN's tells the replica selector to what site a replica/PFN is associated with.

The `pegasus.replica.*.prefer.stagein.sites` property takes precedence over `pegasus.replica.*.ignore.stagein.sites` property i.e. if for a site X, a site Y is specified both in the ignored and the preferred set, then site Y is taken to mean as only a preferred site for a site X.

To use this replica selector set the following property

```
pegasus.selector.replica      Restricted
```

Regex

This replica selector allows the user allows the user to specific regex expressions that can be used to rank various PFN's returned from the Replica Catalog for a particular LFN. This replica selector selects the highest ranked PFN i.e the replica with the lowest rank value.

The regular expressions are assigned different rank, that determine the order in which the expressions are employed. The rank values for the regex can expressed in user properties using the property.

```
pegasus.selector.replica.regex.rank.[value]      regex-expression
```

The **[value]** in the above property is an integer value that denotes the rank of an expression with a rank value of 1 being the highest rank.

For example, a user can specify the following regex expressions that will ask Pegasus to prefer file URL's over gsiftp url's from example.isi.edu

```
pegasus.selector.replica.regex.rank.1      file://.*
pegasus.selector.replica.regex.rank.2      gsiftp://example\.\isi\.edu.*
```

User can specify as many regex expressions as they want.

Since Pegasus is in Java , the regex expression support is what Java supports. It is pretty close to what is supported by Perl. More details can be found at <http://java.sun.com/j2se/1.5.0/docs/api/java/util/regex/Pattern.html>

Before applying any regular expressions on the PFN's for a particular LFN that has to be staged to a site X, the file URL's that don't match the site X are explicitly filtered out.

To use this replica selector set the following property

```
pegasus.selector.replica      Regex
```

Local

This replica selector always prefers replicas from the local host (pool attribute set to local) and that start with a file: URL scheme. It is useful, when users want to stagein files to a remote site from the submit host using the Condor file transfer mechanism.

To use this replica selector set the following property

```
pegasus.selector.replica      Default
```

Job Clustering

A large number of workflows executed through the Pegasus Workflow Management System, are composed of several jobs that run for only a few seconds or so. The overhead of running any job on the grid is usually 60 seconds or more. Hence, it makes sense to cluster small independent jobs into a larger job. This is done while mapping an abstract

workflow to an executable workflow. Site specific or transformation specific criteria are taken into consideration while clustering smaller jobs into a larger job in the executable workflow. The user is allowed to control the granularity of this clustering on a per transformation per site basis.

Overview

The abstract workflow is mapped onto the various sites by the Site Selector. This semi executable workflow is then passed to the clustering module. The clustering of the workflow can be either be

- level based (horizontal clustering)
- label based (label clustering)

The clustering module clusters the jobs into larger/clustering jobs, that can then be executed on the remote sites. The execution can either be sequential on a single node or on multiple nodes using MPI. To specify which clustering technique to use the user has to pass the **--cluster** option to **pegasus-plan** .

Generating Clustered Executable Workflow

The clustering of a workflow is activated by passing the **--cluster|-C** option to **pegasus-plan**. The clustering granularity of a particular logical transformation on a particular site is dependant upon the clustering techniques being used. The executable that is used for running the clustered job on a particular site is determined as explained in section 7.

```
#Running pegasus-plan to generate clustered workflows

$ pegasus-plan --dax example.dax --dir ./dags -p siteX --output local
    --cluster [comma separated list of clustering techniques] -verbose

Valid clustering techniques are horizontal and label.
```

The naming convention of submit files of the clustered jobs is **merge_NAME_IDX.sub** . The NAME is derived from the logical transformation name. The IDX is an integer number between 1 and the total number of jobs in a cluster. Each of the submit files has a corresponding input file, following the naming convention **merge_NAME_IDX.in** . The input file contains the respective execution targets and the arguments for each of the jobs that make up the clustered job.

Horizontal Clustering

In case of horizontal clustering, each job in the workflow is associated with a level. The levels of the workflow are determined by doing a modified Breadth First Traversal of the workflow starting from the root nodes. The level associated with a node, is the furthest distance of it from the root node instead of it being the shortest distance as in normal BFS. For each level the jobs are grouped by the site on which they have been scheduled by the Site Selector. Only jobs of same type (txnamespace, txname, txversion) can be clustered into a larger job. To use horizontal clustering the user needs to set the **--cluster** option of **pegasus-plan** to **horizontal** .

Controlling Clustering Granularity

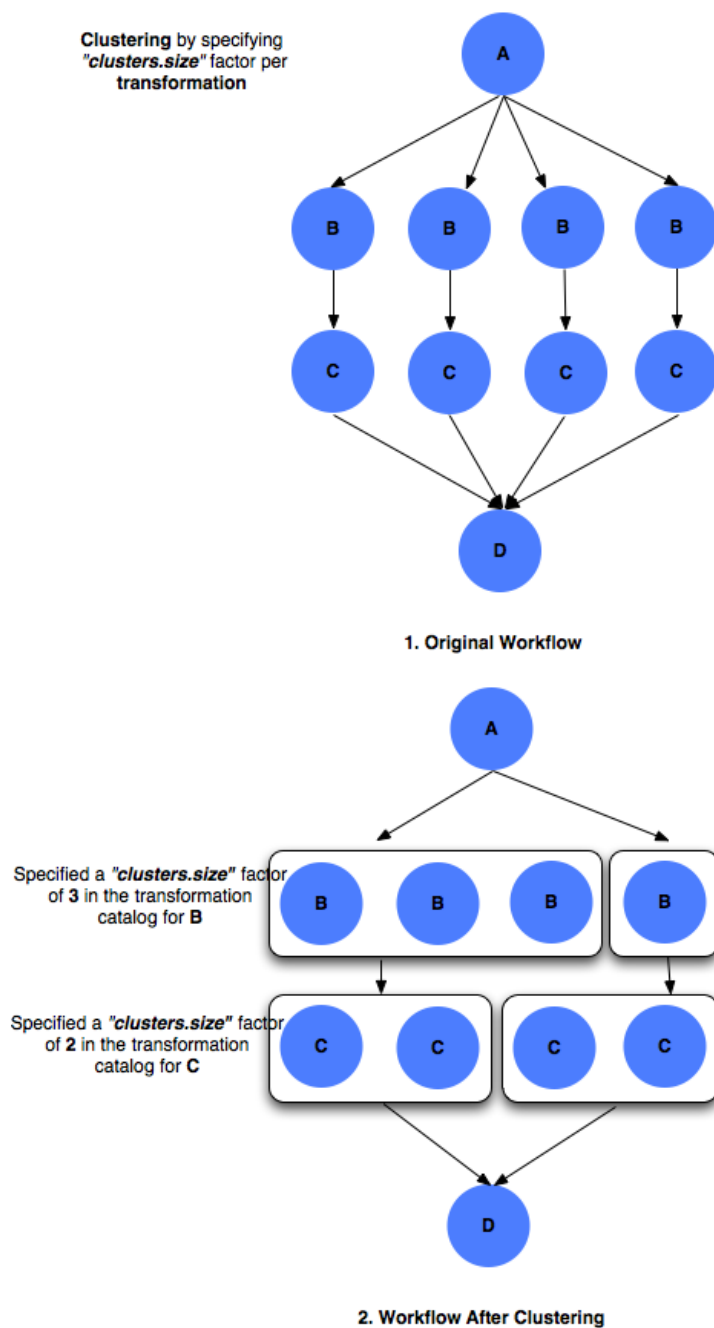

The number of jobs that have to be clustered into a single large job, is determined by the value of two parameters associated with the smaller jobs. Both these parameters are specified by the use of a PEGASUS namespace profile keys. The keys can be specified at any of the placeholders for the profiles (abstract transformation in the DAX, site in the site catalog, transformation in the transformation catalog). The normal overloading semantics apply i.e. profile in transformation catalog overrides the one in the site catalog and that in turn overrides the one in the DAX. The two parameters are described below.

- **clusters.size factor**

The clusters.size factor denotes how many jobs need to be merged into a single clustered job. It is specified via the use of a PEGASUS namespace profile key `“clusters.size”`;. for e.g. if at a particular level, say 4 jobs referring to logical transformation B have been scheduled to a siteX. The clusters.size factor associated with job B for siteX is say 3. This will result in 2 clustered jobs, one composed of 3 jobs and another of 2 jobs. The clusters.size factor can be specified in the transformation catalog as follows

```
#site    transformation    pfn                type                architecture    profiles
```

siteX	B	/shared/PEGASUS/bin/jobB	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.size=3
siteX	C	/shared/PEGASUS/bin/jobC	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.size=2

Figure 10.1. Clustering by clusters.size

- clusters.num factor

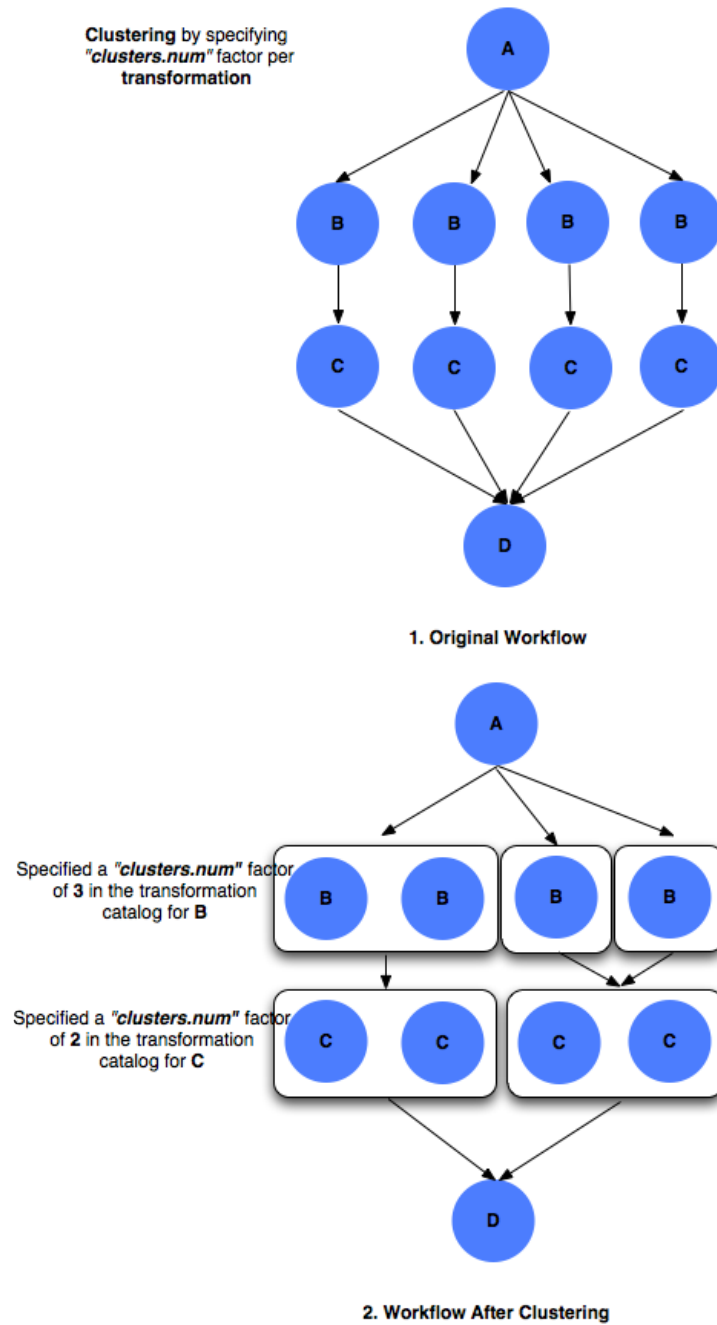

The clusters.num factor denotes how many clustered jobs does the user want to see per level per site. It is specified via the use of a PEGASUS namespace profile key “clusters.num”. for e.g. if at a particular level, say 4 jobs referring to logical transformation B have been scheduled to a siteX. The “clusters.num” factor associated with job B for siteX is say 3. This will result in 3 clustered jobs, one composed of 2 jobs and others of a single job each. The clusters.num factor in the transformation catalog can be specified as follows

#site	transformation	pfn	type	architecture	profiles
siteX	B	/shared/PEGASUS/bin/jobB	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.num=3
siteX	C	/shared/PEGASUS/bin/jobC	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.num=2

In the case, where both the factors are associated with the job, the clusters.num value supersedes the clusters.size value.

#site	transformation	pfn	type	architecture	profiles
siteX	B	/shared/PEGASUS/bin/jobB	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.size=3,clusters.num=3

In the above case the jobs referring to logical transformation B scheduled on siteX will be clustered on the basis of “clusters.num” value. Hence, if there are 4 jobs referring to logical transformation B scheduled to siteX, then 3 clustered jobs will be created.

Figure 10.2. Clustering by clusters.num

Runtime Clustering

Workflows often consist of jobs of same type, but have varying run times. Two or more instances of the same job, with varying inputs can differ significantly in their runtimes. A simple way to think about this is running the same program on two distinct input sets, where one input is smaller (1 MB) as compared to the other which is 10 GB in size. In such a case the two jobs will have significantly differing run times. When such jobs are clustered using horizontal clustering, the benefits of job clustering may be lost if all smaller jobs get clustered together, while the larger jobs are clustered together. In such scenarios it would be beneficial to be able to cluster jobs together such that all clustered jobs have similar runtimes.

In case of runtime clustering, jobs in the workflow are associated with a level. The levels of the workflow are determined in the same manner as in horizontal clustering. For each level the jobs are grouped by the site on which they have been scheduled by the Site Selector. Only jobs of same type (txnamespace, txname, txversion) can be clustered into a larger job. To use runtime clustering the user needs to set the **--cluster** option of **pegasus-plan** to **horizontal**.

Basic Algorithm of grouping jobs into clusters is as follows

```
// cluster.maxruntime - Is the maximum runtime for which the clustered job should run.
// j.runtime - Is the runtime of the job j.
1. Create a set of jobs of the same type (txnamespace, txname, txversion), and that run on the same
   site.
2. Sort the jobs in decreasing order of their runtime.
3. For each job j, repeat
   a. If j.runtime > cluster.maxruntime then
       ignore j.
   // Sum of runtime of jobs already in the bin + j.runtime <= cluster.maxruntime
   b. If j can be added to any existing bin (clustered job) then
       Add j to bin
   Else
       Add a new bin
       Add job j to newly added bin
```

The runtime of a job, and maximum runtime for which a clustered jobs should run, is determined by the value of two parameters associated with the jobs.

- **runtime**

expected runtime for a job

- **clusters.maxruntime**

maxruntime for the clustered job

Both these parameters are specified by the use of a PEGASUS namespace profile keys. The keys can be specified at any of the placeholders for the profiles (abstract transformation in the DAX, site in the site catalog, transformation in the transformation catalog). The normal overloading semantics apply i.e. profile in transformation catalog overrides the one in the site catalog and that in turn overrides the one in the DAX. The two parameters are described below.

#site	transformation	pfname	type	architecture	profiles
siteX	B	/shared/PEGASUS/bin/jobB	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.maxruntime=250, runtime=100
siteX	C	/shared/PEGASUS/bin/jobC	INSTALLED	INTEL32::LINUX	PEGASUS::clusters.maxruntime=300, runtime=100

Figure 10.3. Clustering by runtime

In the above case the jobs referring to logical transformation B scheduled on siteX will be clustered such that all clustered jobs will run approximately for the same duration specified by the *clusters.maxruntime* property. In the

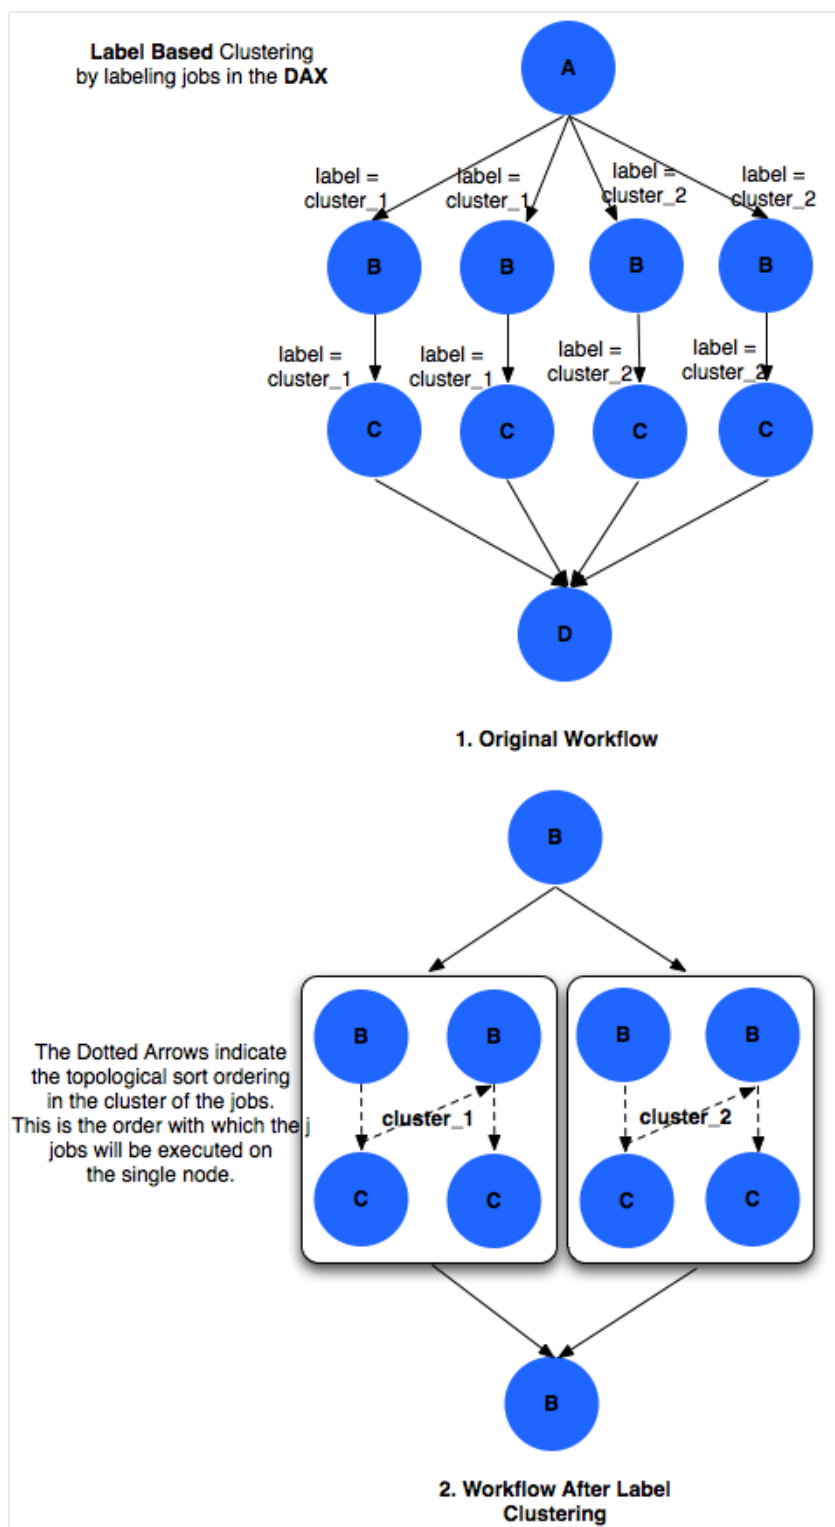

above case we assume all jobs referring to transformation B run for 100 seconds. For jobs with significantly differing runtime, the runtime property will be associated with the jobs in the DAX.

In addition to the above two profiles, we need to inform pegasus-plan to use runtime clustering. This is done by setting the following property .

<code>pegasus.clusterer.preference</code>	<code>Runtime</code>
---	----------------------

Label Clustering

In label based clustering, the user labels the workflow. All jobs having the same label value are clustered into a single clustered job. This allows the user to create clusters or use a clustering technique that is specific to his workflows. If there is no label associated with the job, the job is not clustered and is executed as is

Figure 10.4. Label-based clustering

Since, the jobs in a cluster in this case are not independent, it is important the jobs are executed in the correct order. This is done by doing a topological sort on the jobs in each cluster. To use label based clustering the user needs to set the `--cluster` option of **pegasus-plan** to label.

Labelling the Workflow

The labels for the jobs in the workflow are specified by associated **pegasus** profile keys with the jobs during the DAX generation process. The user can choose which profile key to use for labeling the workflow. By default, it is assumed that the user is using the PEGASUS profile key label to associate the labels. To use another key, in the **pegasus** namespace the user needs to set the following property

- **pegasus.clusterer.label.key**

For example if the user sets **pegasus.clusterer.label.key** to **user_label** then the job description in the DAX looks as follows

```
<adag >
...
<job id="ID000004" namespace="app" name="analyze" version="1.0" level="1" >
  <argument>-a bottom -T60 -i <filename file="user.f.c1"/> -o <filename file="user.f.d"/></
argument>
  <profile namespace="pegasus" key="user_label">p1</profile>
  <uses file="user.f.c1" link="input" dontRegister="false" dontTransfer="false"/>
  <uses file="user.f.c2" link="input" dontRegister="false" dontTransfer="false"/>
  <uses file="user.f.d" link="output" dontRegister="false" dontTransfer="false"/>
</job>
...
</adag>
```

- The above states that the **pegasus** profiles with key as **user_label** are to be used for designating clusters.
- Each job with the same value for **pegasus** profile key **user_label** appears in the same cluster.

Recursive Clustering

In some cases, a user may want to use a combination of clustering techniques. For e.g. a user may want some jobs in the workflow to be horizontally clustered and some to be label clustered. This can be achieved by specifying a comma separated list of clustering techniques to the **--cluster** option of **pegasus-plan**. In this case the clustering techniques are applied one after the other on the workflow in the order specified on the command line.

For example

```
$ pegasus-plan --dax example.dax --dir ./dags --cluster label,horizontal -s siteX --output local --
verbose
```

Figure 10.5. Recursive clustering

Execution of the Clustered Job

The execution of the clustered job on the remote site, involves the execution of the smaller constituent jobs either

- **sequentially on a single node of the remote site**

The clustered job is executed using **pegasus-cluster**, a wrapper tool written in C that is distributed as part of the PEGASUS. It takes in the jobs passed to it, and ends up executing them sequentially on a single node. To use pegasus-cluster for executing any clustered job on a siteX, there needs to be an entry in the transformation catalog for an executable with the logical name seqexec and namespace as pegasus.

#site	transformation	pfn	type	architecture	profiles
siteX	pegasus::seqexec	/usr/pegasus/bin/pegasus-cluster	INSTALLED		INTEL32::LINUX
NULL					

If the entry is not specified, Pegasus will attempt create a default path on the basis of the environment profile PEGASUS_HOME specified in the site catalog for the remote site.

- **On multiple nodes of the remote site using MPI based task management tool called Pegasus MPI Cluster (PMC)**

The clustered job is executed using **pegasus-mpi-cluster**, a wrapper MPI program written in C that is distributed as part of the PEGASUS. A PMC job consists of a single master process (this process is rank 0 in MPI parlance) and several worker processes. These processes follow the standard master-worker architecture. The master process manages the workflow and assigns workflow tasks to workers for execution. The workers execute the tasks and return the results to the master. Communication between the master and the workers is accomplished using a simple text-based protocol implemented using MPI_Send and MPI_Recv. PMC relies on a shared filesystem on the remote site to manage the individual tasks stdout and stderr and stage it back to the submit host as part of it's own stdout/stderr.

The input format for PMC is a DAG based format similar to Condor DAGMan's. PMC follows the dependencies specified in the DAG to release the jobs in the right order and executes parallel jobs via the workers when possible. The input file for PMC is automatically generated by the Pegasus Planner when generating the executable workflow. PMC allows for a finer grained control on how each task is executed. This can be enabled by associating the following pegasus profiles with the jobs in the DAX

Table 10.9. Table : Pegasus Profiles that can be associated with jobs in the DAX for PMC

Key	Description
pmc_request_memory	This key is used to set the -m option for pegasus-mpi-cluster. It specifies the amount of memory in MB that a job requires. This profile is usually set in the DAX for each job.
pmc_request_cpus	This key is used to set the -c option for pegasus-mpi-cluster. It specifies the number of cpu's that a job requires. This profile is usually set in the DAX for each job.
pmc_priority	This key is used to set the -p option for pegasus-mpi-cluster. It specifies the priority for a job . This profile is usually set in the DAX for each job. Negative values are allowed for priorities.
pmc_task_arguments	The key is used to pass any extra arguments to the PMC task during the planning time. They are added to the very end of the argument string constructed for the task in the PMC file. Hence, allows for overriding of any argument constructed by the planner for any particular task in the PMC job.

Refer to the pegasus-mpi-cluster man page in the command line tools chapter to know more about PMC and how it schedules individual tasks.

It is recommended to have a pegasus::mpiexec entry in the transformation catalog to specify the path to PMC on the remote and specify the relevant globus profiles such as xcount, host_xcount and maxwalltime to control size of the MPI job.

#site	transformation	pfm	type	architecture	profiles
siteX	pegasus::mpiexec	/usr/pegasus/bin/pegasus-mpi-cluster	INSTALLED	INTEL32::LINUX	
	globus::xcount=32;globus::host_xcount=1				

If the entry is not specified, Pegasus will attempt create a default path on the basis of the environment profile PEGASUS_HOME specified in the site catalog for the remote site.

Tip

Users are encouraged to use label based clustering in conjunction with PMC

Specification of Method of Execution for Clustered Jobs

The method execution of the clustered job(whether to launch via mpiexec or seqexec) can be specified

1. globally in the properties file

The user can set a property in the properties file that results in all the clustered jobs of the workflow being executed by the same type of executable.

```
#PEGASUS PROPERTIES FILE
pegasus.clusterer.job.aggregator seqexec|mpiexec
```

In the above example, all the clustered jobs on the remote sites are going to be launched via the property value, as long as the property value is not overridden in the site catalog.

2. associating profile key job.aggregator with the site in the site catalog

```
<site handle="siteX" gridlaunch = "/shared/PEGASUS/bin/kickstart">
  <profile namespace="env" key="GLOBUS_LOCATION" >/home/shared/globus</profile>
  <profile namespace="env" key="LD_LIBRARY_PATH">/home/shared/globus/lib</profile>
  <profile namespace="pegasus" key="job.aggregator" >seqexec</profile>
  <lrc url="rls://siteX.edu" />
  <gridftp url="gsiftp://siteX.edu/" storage="/home/shared/work" major="2" minor="4"
  patch="0" />
  <jobmanager universe="transfer" url="siteX.edu/jobmanager-fork" major="2" minor="4"
  patch="0" />
  <jobmanager universe="vanilla" url="siteX.edu/jobmanager-condor" major="2" minor="4"
  patch="0" />
  <workdirectory >/home/shared/storage</workdirectory>
</site>
```

In the above example, all the clustered jobs on a siteX are going to be executed via seqexec, as long as the value is not overridden in the transformation catalog.

3. associating profile key job.aggregator with the transformation that is being clustered, in the transformation catalog

#site	transformation	pfm	type	architecture	profiles
siteX	B	/shared/PEGASUS/bin/jobB	INSTALLED	INTEL32::LINUX	
	pegasus::clusters.size=3,job.aggregator=mpiexec				

In the above example, all the clustered jobs that consist of transformation B on siteX will be executed via mpiexec.

Note

The clustering of jobs on a site only happens only if

- there exists an entry in the transformation catalog for the clustering executable that has been determined by the above 3 rules
- the number of jobs being clustered on the site are more than 1

Outstanding Issues

1. Label Clustering

More rigorous checks are required to ensure that the labeling scheme applied by the user is valid.

Data Transfers

As part of the Workflow Mapping Process, Pegasus does data management for the executable workflow . It queries a Replica Catalog to discover the locations of the input datasets and adds data movement and registration nodes in the workflow to

1. stage-in input data to the staging sites (a site associated with the compute job to be used for staging. In the shared filesystem setup, staging site is the same as the execution sites where the jobs in the workflow are executed)
2. stage-out output data generated by the workflow to the final storage site.
3. stage-in intermediate data between compute sites if required.
4. data registration nodes to catalog the locations of the output data on the final storage site into the replica catalog.

The separate data movement jobs that are added to the executable workflow are responsible for staging data to a workflow specific directory accessible to the staging server on a staging site associated with the compute sites. Depending on the data staging configuration, the staging site for a compute site is the compute site itself. In the default case, the staging server is usually on the headnode of the compute site and has access to the shared filesystem between the worker nodes and the head node. Pegasus adds a directory creation job in the executable workflow that creates the workflow specific directory on the staging server.

In addition to data, Pegasus does transfer user executables to the compute sites if the executables are not installed on the remote sites before hand. This chapter gives an overview of how transfers of data and executables is managed in Pegasus.

Data Staging Configuration

Pegasus can be broadly setup to run workflows in the following configurations

- **Shared File System**

This setup applies to where the head node and the worker nodes of a cluster share a filesystem. Compute jobs in the workflow run in a directory on the shared filesystem.

- **NonShared FileSystem**

This setup applies to where the head node and the worker nodes of a cluster don't share a filesystem. Compute jobs in the workflow run in a local directory on the worker node

- **Condor Pool Without a shared filesystem**

This setup applies to a condor pool where the worker nodes making up a condor pool don't share a filesystem. All data IO is achieved using Condor File IO. This is a special case of the non shared filesystem setup, where instead of using pegasus-transfer to transfer input and output data, Condor File IO is used.

For the purposes of data configuration various sites, and directories are defined below.

1. Submit Host

The host from where the workflows are submitted . This is where Pegasus and Condor DAGMan are installed. This is referred to as the "**local**" site in the site catalog .

2. Compute Site

The site where the jobs mentioned in the DAX are executed. There needs to be an entry in the Site Catalog for every compute site. The compute site is passed to pegasus-plan using **--sites** option

3. Staging Site

A site to which the separate transfer jobs in the executable workflow (jobs with stage_in , stage_out and stage_inter prefixes that Pegasus adds using the transfer refiners) stage the input data to and the output data from to transfer to the final output site. Currently, the staging site is always the compute site where the jobs execute.

4. Output Site

The output site is the final storage site where the users want the output data from jobs to go to. The output site is passed to pegasus-plan using the **--output** option. The stageout jobs in the workflow stage the data from the staging site to the final storage site.

5. Input Site

The site where the input data is stored. The locations of the input data are catalogued in the Replica Catalog, and the pool attribute of the locations gives us the site handle for the input site.

6. Workflow Execution Directory

This is the directory created by the create dir jobs in the executable workflow on the Staging Site. This is a directory per workflow per staging site. Currently, the Staging site is always the Compute Site.

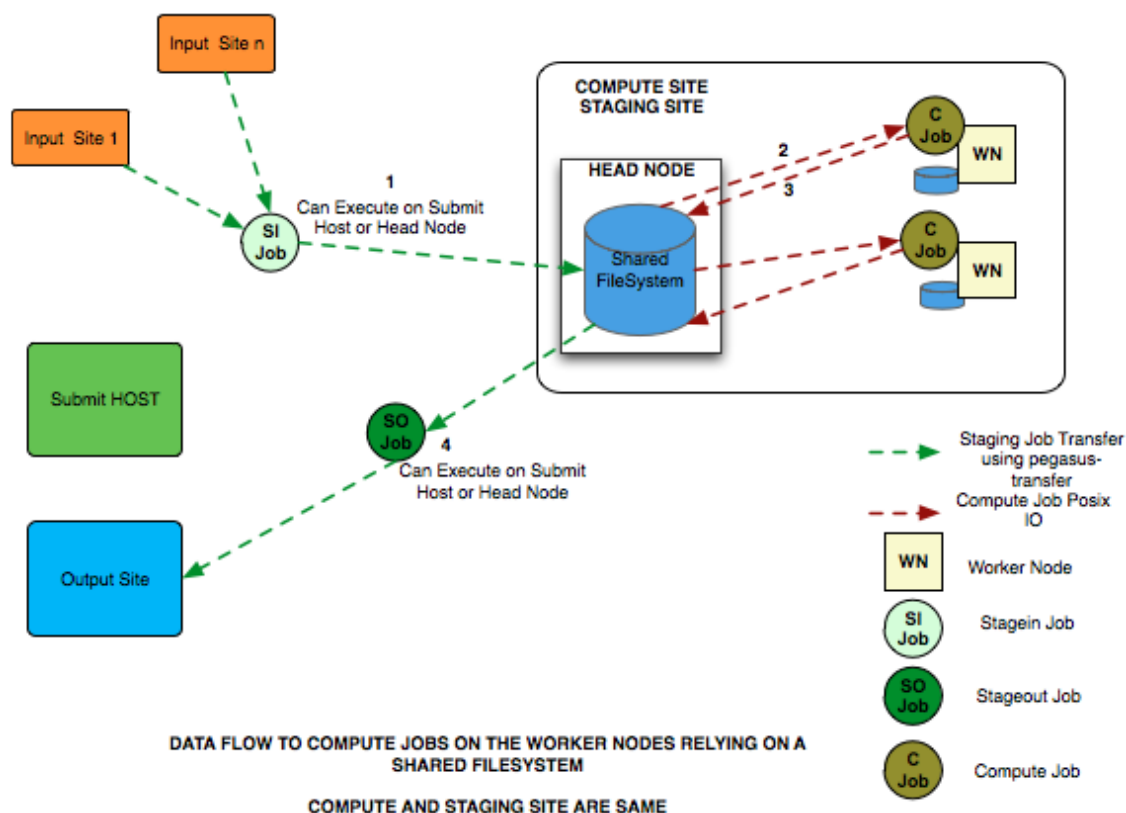

7. Worker Node Directory

This is the directory created on the worker nodes per job usually by the job wrapper that launches the job.

Shared File System

By default Pegasus is setup to run workflows in the shared file system setup, where the worker nodes and the head node of a cluster share a filesystem.

Figure 10.6. Shared File System Setup

The data flow is as follows in this case

1. Stagein Job executes (either on Submit Host or Head Node) to stage in input data from Input Sites (1---n) to a workflow specific execution directory on the shared filesystem.
2. Compute Job starts on a worker node in the workflow execution directory. Accesses the input data using Posix IO
3. Compute Job executes on the worker node and writes out output data to workflow execution directory using Posix IO
4. Stageout Job executes (either on Submit Host or Head Node) to stage out output data from the workflow specific execution directory to a directory on the final output site.

Tip

Set `pegasus.data.configuration` to `shareddfs` to run in this configuration.

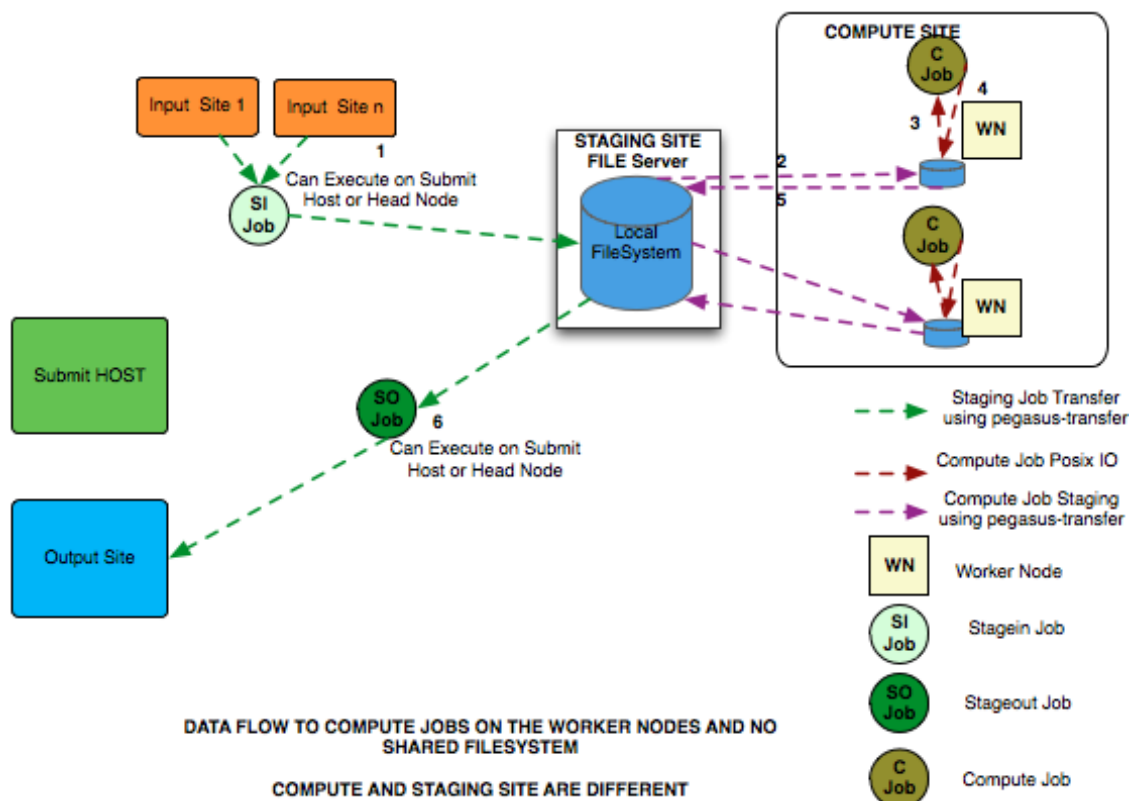

Non Shared Filesystem

In this setup , Pegasus runs workflows on local file-systems of worker nodes with the the worker nodes not sharing a filesystem. The data transfers happen between the worker node and a staging / data coordination site. The staging site server can be a file server on the head node of a cluster or can be on a separate machine.

Setup

- compute and staging site are the different
- head node and worker nodes of compute site don't share a filesystem
- Input Data is staged from remote sites.
- Remote Output Site i.e site other than compute site. Can be submit host.

Figure 10.7. Non Shared Filesystem Setup

The data flow is as follows in this case

1. Stagein Job executes (either on Submit Host or on staging site) to stage in input data from Input Sites (1---n) to a workflow specific execution directory on the staging site.
2. Compute Job starts on a worker node in a local execution directory. Accesses the input data using pegasus transfer to transfer the data from the staging site to a local directory on the worker node
3. The compute job executes in the worker node, and executes on the worker node.
4. The compute Job writes out output data to the local directory on the worker node using Posix IO
5. Output Data is pushed out to the staging site from the worker node using pegasus-transfer.
6. Stageout Job executes (either on Submit Host or staging site) to stage out output data from the workflow specific execution directory to a directory on the final output site.

In this case, the compute jobs are wrapped as PegasusLite instances.

This mode is especially useful for running in the cloud environments where you don't want to setup a shared filesystem between the worker nodes. Running in that mode is explained in detail here.

Tip

Set **pegasus.data.configuration** to **nonsharedfs** to run in this configuration. The staging site can be specified using the **--staging-site** option to pegasus-plan.

In this setup, Pegasus always stages the input files through the staging site i.e the stage-in job stages in data from the input site to the staging site. The PegasusLite jobs that start up on the worker nodes, then pull the input data from the staging site for each job. In some cases, it might be useful to setup the PegasusLite jobs to pull input data directly from the input site without going through the staging server. This is based on the assumption that the worker nodes can access the input site. Starting 4.3 release, users can enable this. However, you should be aware that the access to the input site is no longer throttled (as in case of stage in jobs). If large number of compute jobs start at the same time in a workflow, the input server will see a connection from each job.

Tip

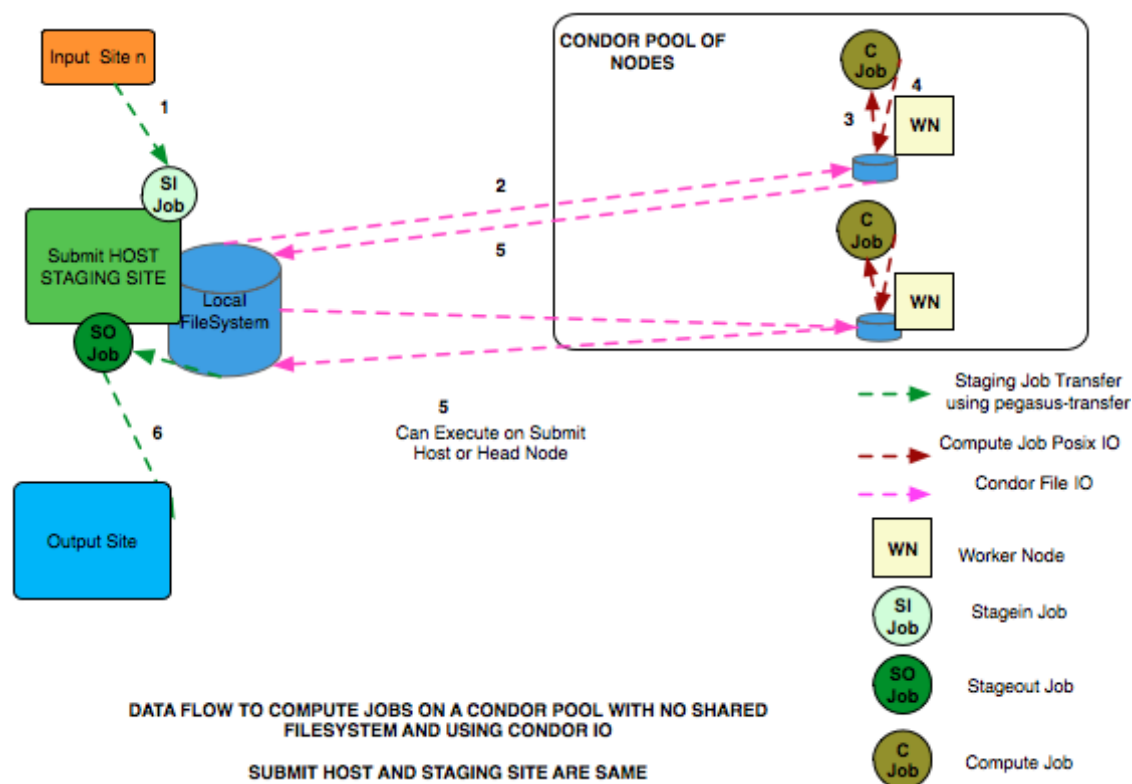

Set **pegasus.transfer.bypass.input.staging** to **true** to enable the bypass of staging of input files via the staging server.

Condor Pool Without a Shared Filesystem

This setup applies to a condor pool where the worker nodes making up a condor pool don't share a filesystem. All data IO is achieved using Condor File IO. This is a special case of the non shared filesystem setup, where instead of using pegasus-transfer to transfer input and output data, Condor File IO is used.

Setup

- Submit Host and staging site are same
- head node and worker nodes of compute site don't share a filesystem
- Input Data is staged from remote sites.
- Remote Output Site i.e site other than compute site. Can be submit host.

Figure 10.8. Condor Pool Without a Shared Filesystem

The data flow is as follows in this case

1. Stagein Job executes on the submit host to stage in input data from Input Sites (1---n) to a workflow specific execution directory on the submit host
2. Compute Job starts on a worker node in a local execution directory. Before the compute job starts, Condor transfers the input data for the job from the workflow execution directory on the submit host to the local execution directory on the worker node.
3. The compute job executes in the worker node, and executes on the worker node.
4. The compute Job writes out output data to the local directory on the worker node using Posix IO
5. When the compute job finishes, Condor transfers the output data for the job from the local execution directory on the worker node to the workflow execution directory on the submit host.
6. Stageout Job executes (either on Submit Host or staging site) to stage out output data from the workflow specific execution directory to a directory on the final output site.

In this case, the compute jobs are wrapped as PegasusLite instances.

This mode is especially useful for running in the cloud environments where you don't want to setup a shared filesystem between the worker nodes. Running in that mode is explained in detail here.

Tip

Set **pegasus.data.configuration** to **condorio** to run in this configuration. In this mode, the staging site is automatically set to site **local**

In this setup, Pegasus always stages the input files through the submit host i.e the stage-in job stages in data from the input site to the submit host (local site). The input data is then transferred to remote worker nodes from the submit

host using Condor file transfers. In the case, where the input data is locally accessible at the submit host i.e the input site and the submit host are the same, then it is possible to bypass the creation of separate stage in jobs that copy the data to the workflow specific directory on the submit host. Instead, Condor file transfers can be setup to transfer the input files directly from the locally accessible input locations (file URL's with site attribute set to local) specified in the replica catalog. Starting 4.3 release, users can enable this.

Tip

Set **pegasus.transfer.bypass.input.staging** to **true** to bypass the creation of separate stage in jobs.

Local versus Remote Transfers

As far as possible, Pegasus will ensure that the transfer jobs added to the executable workflow are executed on the submit host. By default, Pegasus will schedule a transfer to be executed on the remote staging site only if there is no way to execute it on the submit host. For e.g if the file server specified for the staging site/compute site is a file server, then Pegasus will schedule all the stage in data movement jobs on the compute site to stage-in the input data for the workflow. Another case would be if a user has symlinking turned on. In that case, the transfer jobs that symlink against the input data on the compute site, will be executed remotely (on the compute site).

Users can specify the property **pegasus.transfer.*.remote.sites** to change the default behaviour of Pegasus and force pegasus to run different types of transfer jobs for the sites specified on the remote site. The value of the property is a comma separated list of compute sites for which you want the transfer jobs to run remotely.

The table below illustrates all the possible variations of the property.

Table 10.10. Property Variations for pegasus.transfer.*.remote.sites

Property Name	Applies to
pegasus.transfer.stagein.remote.sites	the stage in transfer jobs
pegasus.transfer.stageout.remote.sites	the stage out transfer jobs
pegasus.transfer.inter.remote.sites	the inter site transfer jobs
pegasus.transfer.*.remote.sites	all types of transfer jobs

The prefix for the transfer job name indicates whether the transfer job is to be executed locally (on the submit host) or remotely (on the compute site). For example stage_in_local_ in a transfer job name stage_in_local_isi_viz_0 indicates that the transfer job is a stage in transfer job that is executed locally and is used to transfer input data to compute site isi_viz. The prefix naming scheme for the transfer jobs is **[stage_in|stage_out|inter]_[local|remote]_**.

Symlinking Against Input Data

If input data for a job already exists on a compute site, then it is possible for Pegasus to symlink against that data. In this case, the remote stage in transfer jobs that Pegasus adds to the executable workflow will symlink instead of doing a copy of the data.

Pegasus determines whether a file is on the same site as the compute site, by inspecting the pool attribute associated with the URL in the Replica Catalog. If the pool attribute of an input file location matches the compute site where the job is scheduled, then that particular input file is a candidate for symlinking.

For Pegasus to symlink against existing input data on a compute site, following must be true

1. Property **pegasus.transfer.links** is set to **true**
2. The input file location in the Replica Catalog has the pool attribute matching the compute site.

Tip

To confirm if a particular input file is symlinked instead of being copied, look for the destination URL for that file in stage_in_remote*.in file. The destination URL will start with symlink:// .

In the symlinking case, Pegasus strips out URL prefix from a URL and replaces it with a file URL.

For example if a user has the following URL catalogued in the Replica Catalog for an input file `f.input`

```
f.input    gsiftp://server.isi.edu/shared/storage/input/data/f.input pool="isi"
```

and the compute job that requires this file executes on a compute site named `isi` , then if symlinking is turned on the data stage in job (`stage_in_remote_viz_0`) will have the following source and destination specified for the file

```
#viz viz
file:///shared/storage/input/data/f.input    symlink:///shared-scratch/workflow-exec-dir/f.input
```

Addition of Separate Data Movement Nodes to Executable Workflow

Pegasus relies on a Transfer Refiner that comes up with the strategy on how many data movement nodes are added to the executable workflow. All the compute jobs scheduled to a site share the same workflow specific directory. The transfer refiners ensure that only one copy of the input data is transferred to the workflow execution directory. This is to prevent data clobbering . Data clobbering can occur when compute jobs of a workflow share some input files, and have different stage in transfer jobs associated with them that are staging the shared files to the same destination workflow execution directory.

The default Transfer Refiner used in Pegasus is the Bundle Refiner that allows the user to specify how many local|remote stagein|stageout jobs are created per execution site.

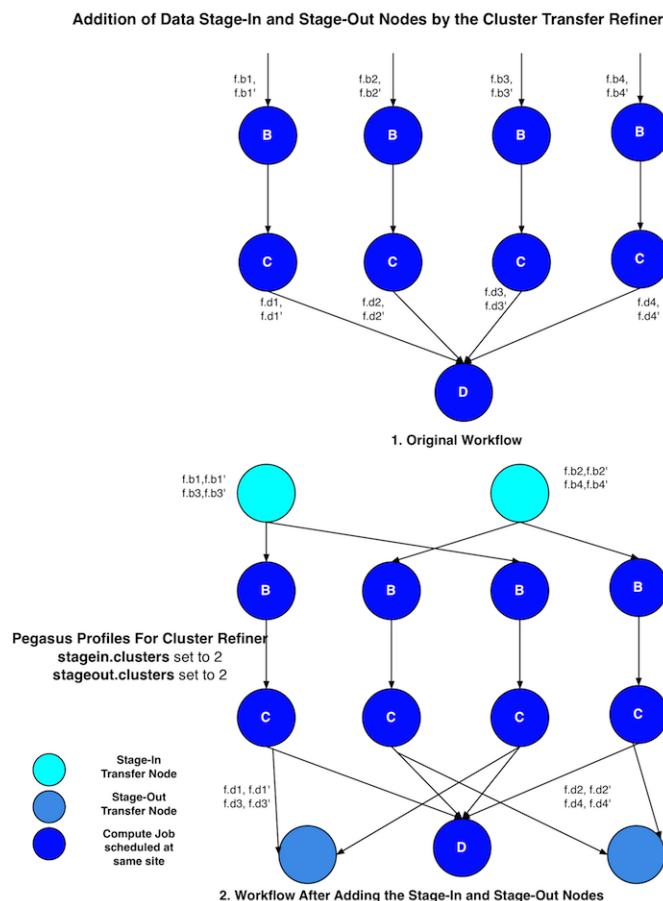

The behavior of the refiner is controlled by specifying certain pegasus profiles

1. either with the execution sites in the site catalog
2. OR globally in the properties file

Table 10.11. Pegasus Profile Keys For the Cluster Transfer Refiner

Profile Key	Description
<code>stagein.clusters</code>	This key determines the maximum number of stage-in jobs that are can executed locally or remotely per compute site per workflow.
<code>stagein.local.clusters</code>	This key provides finer grained control in determining the number of stage-in jobs that are executed locally and are responsible for staging data to a particular remote site.
<code>stagein.remote.clusters</code>	This key provides finer grained control in determining the number of stage-in jobs that are executed remotely on the remote site and are responsible for staging data to it.
<code>stageout.clusters</code>	This key determines the maximum number of stage-out jobs that are can executed locally or remotely per compute site per workflow.
<code>stageout.local.clusters</code>	This key provides finer grained control in determining the number of stage-out jobs that are executed locally and are responsible for staging data from a particular remote site.
<code>stageout.remote.clusters</code>	This key provides finer grained control in determining the number of stage-out jobs that are executed remotely on the remote site and are responsible for staging data from it.

Figure 10.9. Default Transfer Case : Input Data To Workflow Specific Directory on Shared File System

Output Mappers

Starting 4.3 release, Pegasus has support for output mappers, that allow users fine grained control over how the output files on the output site are laid out. By default, Pegasus stages output products to the storage directory specified in the site catalog for the output site. Output mappers allow users finer grained control over where the output files are placed on the output site.

The following mappers are supported currently

1. **Flat** : By default, Pegasus will place the output files in the storage directory specified in the site catalog for the output site.
2. **Fixed** : This mapper allows users to specify an externally accessible url to the storage directory in their properties file. To use this mapper, the following property needs to be set.
 - `pegasus.dir.storage.mapper.fixed.url` an externally accessible URL to the storage directory on the output site e.g. `gsiftp://outputs.isi.edu/shared/outputs`

Note: For hierarchal workflows, the above property needs to be set separately for each dax job, if you want the sub workflow outputs to goto a different directory.

3. **Hashed** : This mapper results in the creation of a deep directory structure on the output site, while populating the results. The base directory on the remote end is determined from the site catalog. Depending on the number of files being staged to the remote site a Hashed File Structure is created that ensures that only 256 files reside in one

directory. To create this directory structure on the storage site, Pegasus relies on the directory creation feature of the underlying file servers such as theGrid FTP server, which appeared in globus 4.0.x

4. **Replica:** This mapper determines the path for an output file on the output site by querying an output replica catalog. The output site is one that is passed on the command line. The output replica catalog can be configured by specifying the properties

- `pegasus.dir.storage.mapper.replica` Regex|File
- `pegasus.dir.storage.mapper.replica.file` the RC file at the backend to use

Tip

The mappers can be configured by setting the property **pegasus.dir.storage.mapper**

Note

The Fixed mapper will be available starting 4.3.1 release.

Executable Used for Transfer Jobs

Pegasus refers to a python script called **pegasus-transfer** as the executable in the transfer jobs to transfer the data. `pegasus-transfer` is a python based wrapper around various transfer clients . `pegasus-transfer` looks at source and destination url and figures out automatically which underlying client to use. `pegasus-transfer` is distributed with the PEGASUS and can be found at `$PEGASUS_HOME/bin/pegasus-transfer`.

Currently, `pegasus-transfer` interfaces with the following transfer clients

Table 10.12. Transfer Clients interfaced to by `pegasus-transfer`

Transfer Client	Used For
<code>globus-url-copy</code>	staging files to and from a gridftp server.
<code>lcg-copy</code>	staging files to and from a SRM server.
<code>wget</code>	staging files from a HTTP server.
<code>cp</code>	copying files from a POSIX filesystem .
<code>ln</code>	symlinking against input files.
<code>pegasus-s3/s3cmd</code>	staging files to and from s3 bucket in the amazon cloud
<code>scp</code>	staging files using scp
<code>iget</code>	staging files to and from a irods server.

For remote sites, Pegasus constructs the default path to `pegasus-transfer` on the basis of `PEGASUS_HOME` env profile specified in the site catalog. To specify a different path to the `pegasus-transfer` client , users can add an entry into the transformation catalog with fully qualified logical name as **pegasus::pegasus-transfer**

Executables used for Directory Creation and Cleanup Jobs

Starting 4.0, Pegasus has changed the way how the scratch directories are created on the staging site. The planner now prefers to schedule the directory creation and cleanup jobs locally. The jobs refer to python based tools, that call out to protocol specific clients to determine what client is picked up. For protocols, where specific remote cleanup and directory creation clients don't exist (for example gridftp), the python tools rely on the corresponding transfer tool to create a directory by initiating a transfer of an empty file. The python clients used to create directories and remove files are called

- `pegasus-create-dir`
- `pegasus-cleanup`

Both these clients inspect the URL's to determine what underlying client to pick up.

Table 10.13. Clients interfaced to by pegasus-create-dir

Client	Used For
globus-url-copy	to create directories against a gridftp/ftp server
srn-mkdir	to create directories against a SRM server.
mkdir	to create a directory on the local filesystem
pegasus-s3	to create a s3 bucket in the amazon cloud
scp	staging files using scp
imkdir	to create a directory against an IRODS server

Table 10.14. Clients interfaced to by pegasus-cleanup

Client	Used For
globus-url-copy	to remove a file against a gridftp/ftp server. In this case a zero byte file is created
srn-rm	to remove files against a SRM server.
rm	to remove a file on the local filesystem
pegasus-s3	to remove a file from the s3 bucket.
scp	to remove a file against a scp server. In this case a zero byte file is created.
irm	to remove a file against an IRODS server

The only case, where the create dir and cleanup jobs are scheduled to run remotely is when for the staging site, a file server is specified.

Credentials Staging

Pegasus tries to do data staging from localhost by default, but some data scenarios makes some remote jobs do data staging. An example of such a case is when running in nonsharedfs mode. Depending on the transfer protocols used, the job may have to carry credentials to enable these data transfers. To specify where which credential to use and where Pegasus can find it, use environment variable profiles in your site catalog. The supported credential types are X.509 grid proxies, Amazon AWS S3 keys, iRods password and SSH keys.

X.509 Grid Proxies

If the grid proxy is required by transfer jobs, and the proxy is in the standard location, Pegasus will pick the proxy up automatically. For non-standard proxy locations, you can use the X509_USER_PROXY environment variable. Site catalog example:

```
<profile namespace="env" key="X509_USER_PROXY" >/some/location/x509up</profile>
```

Amazon AWS S3

If a workflow is using s3 URLs, Pegasus has to be told where to find the .s3cfg file. This format of the file is described in the pegasus-s3 command line client's man page. For the file to be picked up by the workflow, set the S3CFG environment profile to the location of the file. Site catalog example:

```
<profile namespace="env" key="S3CFG" >/home/user/.s3cfg</profile>
```

iRods Password

If a workflow is using irods URLs, Pegasus has to be given an irodsEnv file. It is a standard file, with the addition of an password attribute. Example:

```
# iRODS personal configuration file.
#
# iRODS server host name:
irodsHost 'iren.renci.org'
# iRODS server port number:
```

```
irodsPort 1259

# Default storage resource name:
irodsDefResource 'renResc'
# Home directory in iRODS:
irodsHome '/tip-renci/home/mats'
# Current directory in iRODS:
irodsCwd '/tip-renci/home/mats'
# Account name:
irodsUserName 'mats'
# Zone:
irodsZone 'tip-renci'

# this is used with Pegasus
irodsPassword 'somesecretpassword'
```

The location of the file can be given to the workflow using the `irodsEnvFile` environment profile. Site catalog example:

```
<profile namespace="env" key="irodsEnvFile" >/home/user/.irods/.irodsEnv</profile>
```

SSH Keys

New in Pegasus 4.0 is the support for data staging with scp using ssh public/private key authentication. In this mode, Pegasus transports a private key with the jobs. The storage machines will have to have the public part of the key listed in `~/.ssh/authorized_keys`.

Warning

SSH keys should be handled in a secure manner. In order to keep your personal ssh keys secure, It is recommended that a special set of keys are created for use with the workflow. Note that Pegasus will not pick up ssh keys automatically. The user will have to specify which key to use with `SSH_PRIVATE_KEY`.

The location of the ssh private key can be specified with the `SSH_PRIVATE_KEY` environment profile. Site catalog example:

```
<profile namespace="env" key="SSH_PRIVATE_KEY" >/home/user/wf/wfsshkey</profile>
```

Staging of Executables

Users can get Pegasus to stage the user executables (executables that the jobs in the DAX refer to) as part of the transfer jobs to the workflow specific execution directory on the compute site. The URL locations of the executables need to be specified in the transformation catalog as the PFN and the type of executable needs to be set to **STAGEABLE** .

The location of a transformation can be specified either in

- DAX in the executables section. More details here .
- Transformation Catalog. More details here .

A particular transformation catalog entry of type **STAGEABLE** is compatible with a compute site only if all the System Information attributes associated with the entry match with the System Information attributes for the compute site in the Site Catalog. The following attributes make up the System Information attributes

1. arch
2. os
3. osrelease
4. osversion

Transformation Mappers

Pegasus has a notion of transformation mappers that determines what type of executables are picked up when a job is executed on a remote compute site. For transfer of executables, Pegasus constructs a soft state map that resides on top of the transformation catalog, that helps in determining the locations from where an executable can be staged to the remote site.

Users can specify the following property to pick up a specific transformation mapper

`pegasus.catalog.transformation.mapper`

Currently, the following transformation mappers are supported.

Table 10.15. Transformation Mappers Supported in Pegasus

Transformation Mapper	Description
Installed	This mapper only relies on transformation catalog entries that are of type INSTALLED to construct the soft state map. This results in Pegasus never doing any transfer of executables as part of the workflow. It always prefers the installed executables at the remote sites
Staged	This mapper only relies on matching transformation catalog entries that are of type STAGEABLE to construct the soft state map. This results in the executable workflow referring only to the staged executables, irrespective of the fact that the executables are already installed at the remote end
All	This mapper relies on all matching transformation catalog entries of type STAGEABLE or INSTALLED for a particular transformation as valid sources for the transfer of executables. This is the most general mode, and results in the constructing the map as a result of the cartesian product of the matches.
Submit	This mapper only on matching transformation catalog entries that are of type STAGEABLE and reside at the submit host (pool local), are used while constructing the soft state map. This is especially helpful, when the user wants to use the latest compute code for his computations on the grid and that relies on his submit host.

Staging of Pegasus Worker Package

Pegasus can optionally stage the pegasus worker package as part of the executable workflow to remote workflow specific execution directory. The pegasus worker package contains the pegasus auxiliary executables that are required on the remote site. If the worker package is not staged as part of the executable workflow, then Pegasus relies on the installed version of the worker package on the remote site. To determine the location of the installed version of the worker package on a remote site, Pegasus looks for an environment profile PEGASUS_HOME for the site in the Site Catalog.

Users can set the following property to true to turn on worker package staging

`pegasus.transfer.worker.package` `true`

By default, when worker package staging is turned on pegasus pulls the compatible worker package from the Pegasus Website. To specify a different worker package location, users can specify the transformation **pegasus::worker** in the transformation catalog with

- type set to STAGEABLE
- System Information attributes of the transformation catalog entry match the System Information attributes of the compute site.
- the PFN specified should be a remote URL that can be pulled to the compute site.

Worker Package Staging in Non Shared Filesystem setup

Worker package staging is automatically set to true, when workflows are setup to run in a non shared filesystem setup i.e. `pegasus.data.configuration` is set to `nonsharedfs` or `condorio`. In these configurations, a `stage_worker` job is created that brings in the worker package to the submit directory of the workflow. For each job, the worker package

is then transferred with the job using Condor File Transfers (**transfer_input_files**). This transfer always happens unless, PEGASUS_HOME is specified in the site catalog for the site on which the job is scheduled to run.

Users can explicitly set the following property to false, to turn off worker package staging by the Planner. This is applicable , when running in the cloud and virtual machines / worker nodes already have the pegasus worker tools installed.

```
pegasus.transfer.worker.package      false
```

Using Amazon S3 as a Staging Site

Pegasus can be configured to use Amazon S3 as a staging site. In this mode, Pegasus transfers workflow inputs from the input site to S3. When a job runs, the inputs for that job are fetched from S3 to the worker node, the job is executed, then the output files are transferred from the worker node back to S3. When the jobs are complete, Pegasus transfers the output data from S3 to the output site.

In order to use S3, it is necessary to create a config file for the S3 transfer client, pegasus-s3. See the man page for details on how to create the config file. You also need to specify S3 as a staging site.

Next, you need to modify your site catalog to tell the location of your s3cfg file. See the section on credential staging.

The following site catalog shows how to specify the location of the s3cfg file on the local site and how to specify an Amazon S3 staging site:

```
<sitecatalog xmlns="http://pegasus.isi.edu/schema/sitecatalog"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://pegasus.isi.edu/schema/sitecatalog
    http://pegasus.isi.edu/schema/sc-3.0.xsd" version="3.0">
  <site handle="local" arch="x86_64" os="LINUX">
    <head-fs>
      <scratch>
        <shared>
          <file-server protocol="file" url="file://" mount-point="/tmp/wf/work"/>
          <internal-mount-point mount-point="/tmp/wf/work"/>
        </shared>
      </scratch>
      <storage>
        <shared>
          <file-server protocol="file" url="file://" mount-point="/tmp/wf/storage"/>
          <internal-mount-point mount-point="/tmp/wf/storage"/>
        </shared>
      </storage>
    </head-fs>
    <profile namespace="env" key="S3CFG"/></home/username/.s3cfg</profile>
  </site>
  <site handle="s3" arch="x86_64" os="LINUX">
    <head-fs>
      <scratch>
        <shared>
          <!-- wf-scratch is the name of the S3 bucket that will be used -->
          <file-server protocol="s3" url="s3://user@amazon" mount-point="/wf-scratch"/>
          <internal-mount-point mount-point="/wf-scratch"/>
        </shared>
      </scratch>
    </head-fs>
  </site>
  <site handle="condorpool" arch="x86_64" os="LINUX">
    <head-fs>
      <scratch/>
      <storage/>
    </head-fs>
    <profile namespace="pegasus" key="style">condor</profile>
    <profile namespace="condor" key="universe">vanilla</profile>
    <profile namespace="condor" key="requirements">(Target.Arch == "X86_64")</profile>
  </site>
</sitecatalog>
```

iRODS data access

iRODS can be used as an input data location, a storage site for intermediate data during workflow execution, or a location for final output data. Pegasus uses a URL notation to identify iRODS files. Example:

```
irods://some-host.org/path/to/file.txt
```

The path to the file is **relative** to the internal iRODS location. In the example above, the path used to refer to the file in iRODS is *path/to/file.txt* (no leading /).

See the section on credential staging for information on how to set up an irodsEnv file to be used by Pegasus.

Hierarchical Workflows

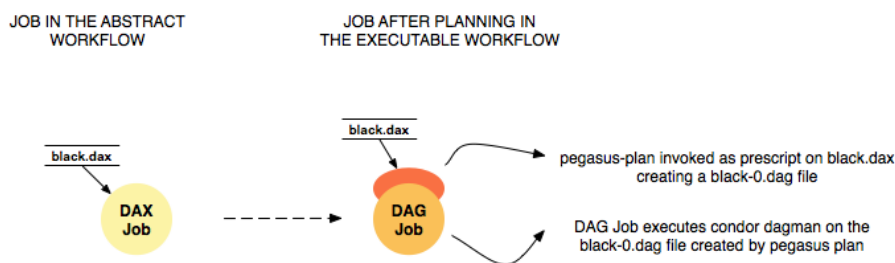

Introduction

The Abstract Workflow in addition to containing compute jobs, can also contain jobs that refer to other workflows. This is useful for running large workflows or ensembles of workflows.

Users can embed two types of workflow jobs in the DAX

1. **daxjob** - refers to a sub workflow represented as a DAX. During the planning of a workflow, the DAX jobs are mapped to condor dagman jobs that have pegasus plan invocation on the dax (referred to in the DAX job) as the prescript.

Figure 10.10. Planning of a DAX Job

2. **dagjob** - refers to a sub workflow represented as a DAG. During the planning of a workflow, the DAG jobs are mapped to condor dagman and refer to the DAG file mentioned in the DAG job.

Figure 10.11. Planning of a DAG Job

Specifying a DAX Job in the DAX

Specifying a DAXJob in a DAX is pretty similar to how normal compute jobs are specified. There are minor differences in terms of the xml element name (dax vs job) and the attributes specified. DAXJob XML specification is described in detail in the chapter on DAX API . An example DAX Job in a DAX is shown below

```
<dax id="ID000002" name="black.dax" node-label="bar" >
  <profile namespace="dagman" key="maxjobs">10</profile>
  <argument>-Xmx1024 -Xms512 -Dpegasus.dir.storage=storagedir -Dpegasus.dir.exec=execdir -o local
-vvvvv --force -s dax_site </argument>
</dax>
```

DAX File Locations

The name attribute in the dax element refers to the LFN (Logical File Name) of the dax file. The location of the DAX file can be catalogued either in the

1. Replica Catalog
2. Replica Catalog Section in the DAX .

Note

Currently, only file url's on the local site (submit host) can be specified as DAX file locations.

Arguments for a DAX Job

Users can specify specific arguments to the DAX Jobs. The arguments specified for the DAX Jobs are passed to the pegasus-plan invocation in the prescript for the corresponding condor dagman job in the executable workflow.

The following options for pegasus-plan are inherited from the pegasus-plan invocation of the parent workflow. If an option is specified in the arguments section for the DAX Job then that overrides what is inherited.

Table 10.16. Options inherited from parent workflow

Option Name	Description
--sites	list of execution sites.

It is highly recommended that users **dont specify** directory related options in the arguments section for the DAX Jobs. Pegasus assigns values to these options for the sub workflows automatically.

1. --relative-dir
2. --dir
3. --relative-submit-dir

Profiles for DAX Job

Users can choose to specify dagman profiles with the DAX Job to control the behavior of the corresponding condor dagman instance in the executable workflow. In the example above maxjobs is set to 10 for the sub workflow.

Execution of the PRE script and Condor DAGMan instance

The pegasus plan that is invoked as part of the prescript to the condor dagman job is executed on the submit host. The log from the output of pegasus plan is redirected to a file (ending with suffix pre.log) in the submit directory of the workflow that contains the DAX Job. The path to pegasus-plan is automatically determined.

The DAX Job maps to a Condor DAGMan job. The path to condor dagman binary is determined according to the following rules -

1. entry in the transformation catalog for condor::dagman for site local, else
2. pick up the value of CONDOR_HOME from the environment if specified and set path to condor dagman as \$CONDOR_HOME/bin/condor_dagman , else
3. pick up the value of CONDOR_LOCATION from the environment if specified and set path to condor dagman as \$CONDOR_LOCATION/bin/condor_dagman , else
4. pick up the path to condor dagman from what is defined in the user's PATH

Tip

It is recommended that user dagman.maxpre in their properties file to control the maximum number of pegasus plan instances launched by each running dagman instance.

Specifying a DAG Job in the DAX

Specifying a DAGJob in a DAX is pretty similar to how normal compute jobs are specified. There are minor differences in terms of the xml element name (dag vs job) and the attributes specified. For DAGJob XML details, see the API Reference chapter . An example DAG Job in a DAX is shown below

```
<dag id="ID000003" name="black.dag" node-label="foo" >
  <profile namespace="dagman" key="maxjobs">10</profile>
  <profile namespace="dagman" key="DIR">/dag-dir/test</profile>
</dag>
```

DAG File Locations

The name attribute in the dag element refers to the LFN (Logical File Name) of the dax file. The location of the DAX file can be catalogued either in the

1. Replica Catalog
2. Replica Catalog Section in the DAX.

Note

Currently, only file url's on the local site (submit host) can be specified as DAG file locations.

Profiles for DAG Job

Users can choose to specify dagman profiles with the DAX Job to control the behavior of the corresponding condor dagman instance in the executable workflow. In the example above, maxjobs is set to 10 for the sub workflow.

The dagman profile DIR allows users to specify the directory in which they want the condor dagman instance to execute. In the example above black.dag is set to be executed in directory /dag-dir/test . The /dag-dir/test should be created beforehand.

File Dependencies Across DAX Jobs

In hierarchal workflows , if a sub workflow generates some output files required by another sub workflow then there should be an edge connecting the two dax jobs. Pegasus will ensure that the prescript for the child sub-workflow, has the path to the cache file generated during the planning of the parent sub workflow. The cache file in the submit directory for a workflow is a textual replica catalog that lists the locations of all the output files created in the remote workflow execution directory when the workflow executes.

This automatic passing of the cache file to a child sub-workflow ensures that the datasets from the same workflow run are used. However, the passing of the locations in a cache file also ensures that Pegasus will prefer them over all

other locations in the Replica Catalog. If you need the Replica Selection to consider locations in the Replica Catalog also, then set the following property.

```
pegasus.catalog.replica.cache.asrc true
```

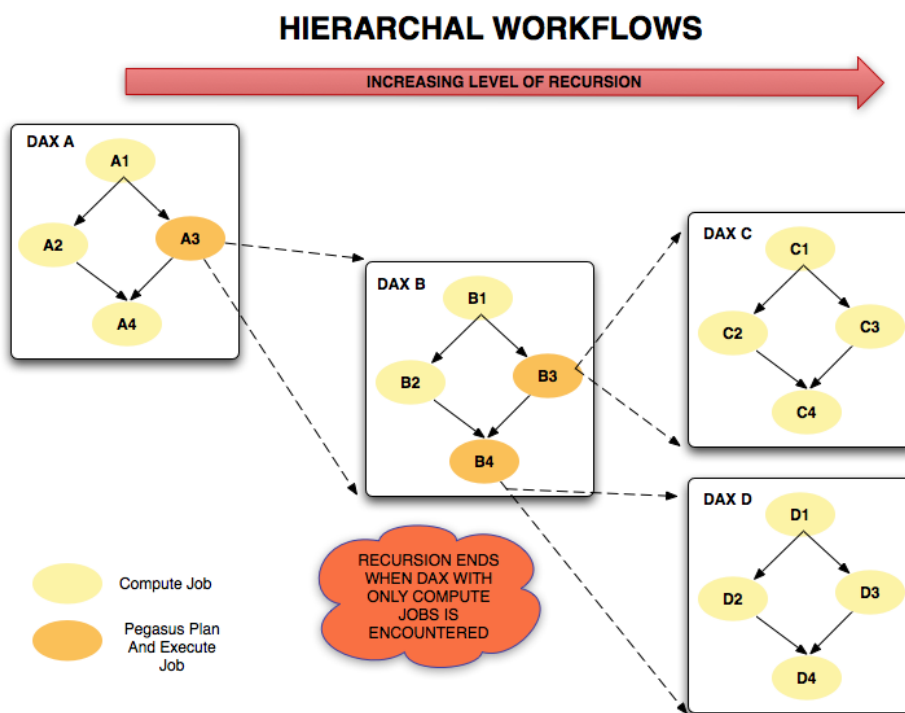

The above is useful in the case, where you are staging out the output files to a storage site, and you want the child sub workflow to stage these files from the storage output site instead of the workflow execution directory where the files were originally created.

Recursion in Hierarchal Workflows

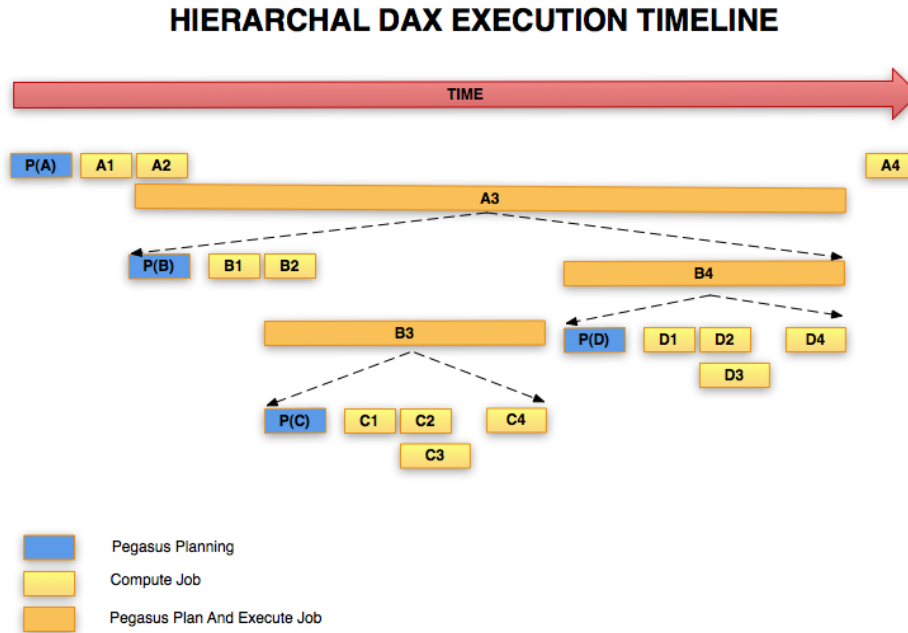

It is possible for a user to add a dax jobs to a dax that already contain dax jobs in them. Pegasus does not place a limit on how many levels of recursion a user can have in their workflows. From Pegasus perspective recursion in hierarchal workflows ends when a DAX with only compute jobs is encountered. However, the levels of recursion are limited by the system resources consumed by the DAGMan processes that are running (each level of nesting produces another DAGMan process).

The figure below illustrates an example with recursion 2 levels deep.

Figure 10.12. Recursion in Hierarchal Workflows

The execution time-line of the various jobs in the above figure is illustrated below.

Figure 10.13. Execution Time-line for Hierarchal Workflows

Example

The Galactic Plane workflow is a Hierarchical workflow of many Montage workflows. For details, see Workflow of Workflows.

Notifications

The Pegasus Workflow Mapper now supports job and workflow level notifications. You can specify in the DAX with the job or the workflow

- the event when the notification needs to be sent
- the executable that needs to be invoked.

The notifications are issued from the submit host by the pegasus-monitor daemon that monitors the Condor logs for the workflow. When a notification is issued, pegasus-monitor while invoking the notifying executable sets certain environment variables that contain information about the job and workflow state.

The Pegasus release comes with default notification clients that send notifications via email or jabber.

Specifying Notifications in the DAX

Currently, you can specify notifications for the jobs and the workflow by the use of invoke elements.

Invoke elements can be sub elements for the following elements in the DAX schema.

- job - to associate notifications with a compute job in the DAX.

- `dax` - to associate notifications with a `dax` job in the DAX.
- `dag` - to associate notifications with a `dag` job in the DAX.
- `executable` - to associate notifications with a job that uses a particular notification

The `invoke` element can be specified at the root element level of the DAX to indicate workflow level notifications.

The `invoke` element may be specified multiple times, as needed. It has a mandatory **when** attribute with the following value set

Table 10.17. Table 1. Invoke Element attributes and meaning.

Enumeration of Values for when attribute	Meaning
never	(default). Never notify of anything. This is useful to temporarily disable an existing notifications.
start	create a notification when the job is submitted.
on_error	after a job finishes with failure (exitcode != 0).
on_success	after a job finishes with success (exitcode == 0).
at_end	after a job finishes, regardless of exitcode.
all	like start and at_end combined.

You can specify multiple `invoke` elements corresponding to same when attribute value in the DAX. This will allow you to have multiple notifications for the same event.

Here is an example that illustrates that.

```
<job id="ID000001" namespace="example" name="mDiffFit" version="1.0"
  node-label="preprocess" >
  <argument>-a top -T 6 -i <file name="f.a"/> -o <file name="f.b1"/></argument>

  <!-- profiles are optional -->
  <profile namespace="execution" key="site">isi_viz</profile>
  <profile namespace="condor" key="getenv">true</profile>

  <uses name="f.a" link="input" register="false" transfer="true" type="data" />
  <uses name="f.b" link="output" register="false" transfer="true" type="data" />

  <!-- 'WHEN' enumeration: never, start, on_error, on_success, on_end, all -->
  <invoke when="start">/path/to/notify1 arg1 arg2</invoke>
  <invoke when="start">/path/to/notify1 arg3 arg4</invoke>
  <invoke when="on_success">/path/to/notify2 arg3 arg4</invoke>
</job>
```

In the above example the executable `notify1` will be invoked twice when a job is submitted (`when="start"`), once with arguments `arg1` and `arg2` and second time with arguments `arg3` and `arg4`.

The DAX Generator API chapter has information about how to add notifications to the DAX using the DAX api's.

Notify File created by Pegasus in the submit directory

Pegasus while planning a workflow writes out a notify file in the submit directory that contains all the notifications that need to be sent for the workflow. `pegasus-monitor` picks up this notifications file to determine what notifications need to be sent and when.

1. ENTITY_TYPE ID NOTIFICATION_CONDITION ACTION

- `ENTITY_TYPE` can be either of the following keywords
 - `WORKFLOW` - indicates workflow level notification
 - `JOB` - indicates notifications for a job in the executable workflow
 - `DAXJOB` - indicates notifications for a DAX Job in the executable workflow

- DAGJOB - indicates notifications for a DAG Job in the executable workflow
- ID indicates the identifier for the entity. It has different meaning depending on the entity type - -
 - workflow - ID is wf_uuid
 - JOB|DAXJOB|DAGJOB - ID is the job identifier in the executable workflow (DAG).
- NOTIFICATION_CONDITION is the condition when the notification needs to be sent. The notification conditions are enumerated in Table 1
- ACTION is what needs to happen when condition is satisfied. It is executable + arguments

2. INVOCATION JOB_IDENTIFIER INV.ID NOTIFICATION_CONDITION ACTION

The INVOCATION lines are only generated for clustered jobs, to specify the finer grained notifications for each constituent job/invocation .

- JOB_IDENTIFIER is the job identifier in the executable workflow (DAG).
- INV.ID indicates the index of the task in the clustered job for which the notification needs to be sent.
- NOTIFICATION_CONDITION is the condition when the notification needs to be sent. The notification conditions are enumerated in Table 1
- ACTION is what needs to happen when condition is satisfied. It is executable + arguments

A sample notifications file generated is listed below.

```
WORKFLOW d2c4f79c-8d5b-4577-8c46-5031f4d704e8 on_error /bin/date1

INVOCATION merge_vahi-preprocess-1.0_PID1_ID1 1 on_success /bin/date_executable
INVOCATION merge_vahi-preprocess-1.0_PID1_ID1 1 on_success /bin/date_executable
INVOCATION merge_vahi-preprocess-1.0_PID1_ID1 1 on_error /bin/date_executable

INVOCATION merge_vahi-preprocess-1.0_PID1_ID1 2 on_success /bin/date_executable
INVOCATION merge_vahi-preprocess-1.0_PID1_ID1 2 on_error /bin/date_executable

DAXJOB subdax_black_ID000003 on_error /bin/date13
JOB analyze_ID00004 on_success /bin/date
```

Configuring pegasus-monitord for notifications

Whenever pegasus-monitord enters a workflow (or sub-workflow) directory, it will read the notifications file generated by Pegasus. Pegasus-monitord will match events in the running workflow against the notifications specified in the notifications file and will initiate the script specified in a notification when that notification matches an event in the workflow. It is important to note that there will be a delay between a certain event happening in the workflow, and pegasus-monitord processing the log file and executing the corresponding notification script.

The following command line options (and properties) can change how pegasus-monitord handles notifications:

- `--no-notifications` (pegasus.monitord.notifications=False): Will disable notifications completely.
- `--notifications-max=nn` (pegasus.monitord.notifications.max=nn): Will limit the number of concurrent notification scripts to nn. Once pegasus-monitord reaches this number, it will wait until one notification script finishes before starting a new one. Notifications happening during this time will be queued by the system. The default number of concurrent notification scripts for pegasus-monitord is 10.
- `--notifications-timeout=nn` (pegasus.monitord.notifications.timeout=nn): This setting is used to change how long will pegasus-monitord wait for a notification script to finish. By default pegasus-monitord will wait for as long as it takes (possibly indefinitely) until a notification script ends. With this option, pegasus-monitord will wait for at most nn seconds before killing the notification script.

It is also important to understand that pegasus-monitord will not issue any notifications when it is executed in replay mode.

Environment set for the notification scripts

Whenever a notification in the notifications file matches an event in the running workflow, pegasus-monitord will run the corresponding script specified in the ACTION field of the notifications file. Pegasus-monitord will set the following environment variables for each notification script is starts:

- **PEGASUS_EVENT**: The NOTIFICATION_CONDITION that caused the notification. In the case of the "all" condition, pegasus-monitord will substitute it for the actual event that caused the match (e.g. "start" or "at_end").
- **PEGASUS_EVENT_TIMESTAMP**: Timestamp in EPOCH format for the event (better for automated processing).
- **PEGASUS_EVENT_TIMESTAMP_ISO**: Same as above, but in ISO format (better for human readability).
- **PEGASUS_SUBMIT_DIR**: The submit directory for the workflow (usually the value from "submit_dir" in the braindump.txt file)
- **PEGASUS_STDOUT**: For workflow notifications, this will correspond to the dagman.out file for that workflow. For job and invocation notifications, this field will contain the output file (stdout) for that particular job instance.
- **PEGASUS_STDERR**: For job and invocation notifications, this field will contain the error file (stderr) for the particular executable job instance. This field does not exist in case of workflow notifications.
- **PEGASUS_WFID**: Contains the workflow id for this notification in the form of DAX_LABEL + DAX_INDEX (from the braindump.txt file).
- **PEGASUS_JOBID**: For workflow notifications, this contains the workflow wf_uuid (from the braindump.txt file). For job and invocation notifications, this field contains the job identifier in the executable workflow (DAG) for the particular notification.
- **PEGASUS_INVID**: Contains the index of the task in the clustered job for the notification.
- **PEGASUS_STATUS**: For workflow notifications, this contains DAGMan's exit code. For job and invocation notifications, this field contains the exit code for the particular job/task. Please note that this field is not present for 'start' notification events.

Default Notification Scripts

Pegasus ships with two reference notification scripts. These can be used as starting point when creating your own notification scripts, or if the default one is all you need, you can use them directly in your workflows. The scripts are:

- **libexec/notification/email** - sends email, including the output from **pegasus-status** (default) or **pegasus-analyzer**.

```
$ ./libexec/notification/email --help
Usage: email [options]

Options:
  -h, --help                show this help message and exit
  -t TO_ADDRESS, --to=TO_ADDRESS
                           The To: email address. Defines the recipient for the
                           notification.
  -f FROM_ADDRESS, --from=FROM_ADDRESS
                           The From: email address. Defaults to the required To:
                           address.
  -r REPORT, --report=REPORT
                           Include workflow report. Valid values are: none
                           pegasus-analyzer pegasus-status (default)
```

- **libexec/notification/jabber** - sends simple notifications to Jabber/GTalk. This can be useful for job failures.

```
$ ./libexec/notification/jabber --help
Usage: jabber [options]

Options:
  -h, --help                show this help message and exit
  -i JABBER_ID, --jabberid=JABBER_ID
                           Your jabber id. Example: user@jabberhost.com
```

```
-p PASSWORD, --password=PASSWORD
    Your jabber password
-s HOST, --host=HOST    Jabber host, if different from the host in your jabber
                        id. For Google talk, set this to talk.google.com
-r RECIPIENT, --recipient=RECIPIENT
    Jabber id of the recipient. Not necessary if you want
    to send to your own jabber id
```

For example, if the DAX generator is written in Python and you want notifications on 'at_end' events (successful or failed):

```
# job level notifications - in this case for at_end events
job.invoke('at_end', pegasus_home + "/libexec/notifications/email --to me@somewhere.edu")
```

Please see the notifications example to see a full workflow using notifications.

Monitoring

Pegasus launches a monitoring daemon called **pegasus-monitor** per workflow (a single daemon is launched if a user submits a hierarchal workflow) . **pegasus-monitor** parses the workflow and job logs in the submit directory and populates to a database. This chapter gives an overview of the **pegasus-monitor** and describes the schema of the runtime database.

pegasus-monitor

Pegasus-monitor is used to follow workflows, parsing the output of DAGMan's dagman.out file. In addition to generating the jobstate.log file, which contains the various states that a job goes through during the workflow execution, **pegasus-monitor** can also be used to mine information from jobs' submit and output files, and either populate a database, or write a file with NetLogger events containing this information. **Pegasus-monitor** can also send notifications to users in real-time as it parses the workflow execution logs.

Pegasus-monitor is automatically invoked by **pegasus-run**, and tracks workflows in real-time. By default, it produces the jobstate.log file, and a SQLite database, which contains all the information listed in the Stampede schema. When a workflow fails, and is re-submitted with a rescue DAG, **pegasus-monitor** will automatically pick up from where it left previously and continue to write the jobstate.log file and populate the database.

If, after the workflow has already finished, users need to re-create the jobstate.log file, or re-populate the database from scratch, **pegasus-monitor**'s **--replay** option should be used when running it manually.

Populating to different backend databases

In addition to SQLite, **pegasus-monitor** supports other types of databases, such as MySQL and Postgres. Users will need to install the low-level database drivers, and can use the **--dest** command-line option, or the **pegasus.monitor.output** property to select where the logs should go.

As an example, the command:

```
$ pegasus-monitor -r diamond-0.dag.dagman.out
```

will launch **pegasus-monitor** in replay mode. In this case, if a jobstate.log file already exists, it will be rotated and a new file will be created. It will also create/use a SQLite database in the workflow's run directory, with the name of diamond-0.stampede.db. If the database already exists, it will make sure to remove any references to the current workflow before it populates the database. In this case, **pegasus-monitor** will process the workflow information from start to finish, including any restarts that may have happened.

Users can specify an alternative database for the events, as illustrated by the following examples:

```
$ pegasus-monitor -r -d mysql://username:userpass@hostname/database_name diamond-0.dag.dagman.out
$ pegasus-monitor -r -d sqlite:///tmp/diamond-0.db diamond-0.dag.dagman.out
```

In the first example, **pegasus-monitor** will send the data to the **database_name** database located at server **hostname**, using the **username** and **userpass** provided. In the second example, **pegasus-monitor** will store the data in the /tmp/diamond-0.db SQLite database.

Note

For absolute paths four slashes are required when specifying an alternative database path in SQLite.

Users should also be aware that in all cases, with the exception of SQLite, the database should exist before **pegasus-monitor** is run (as it creates all needed tables but does not create the database itself).

Finally, the following example:

```
$ pegasus-monitor -r --dest diamond-0.bp diamond-0.dag.dagman.out
```

sends events to the diamond-0.bp file. (please note that in replay mode, any data on the file will be overwritten).

One important detail is that while processing a workflow, **pegasus-monitor** will automatically detect if/when sub-workflows are initiated, and will automatically track those sub-workflows as well. In this case, although **pegasus-monitor** will create a separate jobstate.log file in each workflow directory, the database at the top-level workflow will contain the information from not only the main workflow, but also from all sub-workflows.

Monitoring related files in the workflow directory

Pegasus-monitor generates a number of files in each workflow directory:

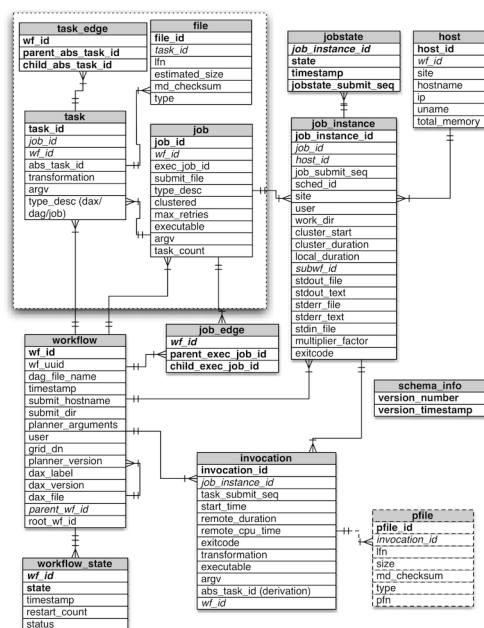

- **jobstate.log**: contains a summary of workflow and job execution.
- **monitor.log**: contains any log messages generated by **pegasus-monitor**. It is not overwritten when it restarts. This file is not generated in replay mode, as all log messages from **pegasus-monitor** are output to the console. Also, when sub-workflows are involved, only the top-level workflow will have this log file. Starting with release 4.0 and 3.1.1, monitor.log file is rotated if it exists already.
- **monitor.started**: contains a timestamp indicating when **pegasus-monitor** was started. This file get overwritten every time **pegasus-monitor** starts.
- **monitor.done**: contains a timestamp indicating when **pegasus-monitor** finished. This file is overwritten every time **pegasus-monitor** starts.
- **monitor.info**: contains **pegasus-monitor** state information, which allows it to resume processing if a workflow does not finish properly and a rescue dag is submitted. This file is erased when **pegasus-monitor** is executed in replay mode.
- **monitor.recover**: contains **pegasus-monitor** state information that allows it to detect that a previous instance of **pegasus-monitor** failed (or was killed) midway through parsing a workflow's execution logs. This file is only present while **pegasus-monitor** is running, as it is deleted when it ends and the **monitor.info** file is generated.
- **monitor.subwf.db**: contains information that aids **pegasus-monitor** to track when sub-workflows fail and are re-planned/re-tried. It is overwritten when **pegasus-monitor** is started in replay mode.
- **monitor-notifications.log**: contains the log file for notification-related messages. Normally, this file only includes logs for failed notifications, but can be populated with all notification information when **pegasus-monitor** is run in verbose mode via the **-v** command-line option.

Overview of the Stampede Database Schema.

Pegasus takes in a DAX which is composed of tasks. Pegasus plans it into a Condor DAG / Executable workflow that consists of Jobs. In case of Clustering, multiple tasks in the DAX can be captured into a single job in the Executable workflow. When DAGMan executes a job, a job instance is populated. Job instances capture information as seen by DAGMan. In case DAGMan retires a job on detecting a failure, a new job instance is populated. When DAGMan finds a job instance has finished, an invocation is associated with job instance. In case of clustered job, multiple invocations will be associated with a single job instance. If a Pre script or Post Script is associated with a job instance, then invocations are populated in the database for the corresponding job instance.

The current schema version is **4.0** that is stored in the schema_info table.

Figure 10.14. Stampede Database Schema

Stampede Schema Upgrade Tool

Starting Pegasus 4.x the monitoring and statistics database schema has changed. If you want to use the pegasus-statistics, pegasus-analyzer and pegasus-plots against a 3.x database you will need to upgrade the schema first using the schema upgrade tool `/usr/share/pegasus/sql/schema_tool.py` or `/path/to/pegasus-4.x/share/pegasus/sql/schema_tool.py`

Upgrading the schema is required for people using the MySQL database for storing their monitoring information if it was setup with 3.x monitoring tools.

If your setup uses the default SQLite database then the new databases run with Pegasus 4.x are automatically created with the correct schema. In this case you only need to upgrade the SQLite database from older runs if you wish to query them with the newer clients.

To upgrade the database

For SQLite Database

```
cd /to/the/workflow/directory/with/3.x.monitordb
```

Check the db version

```
/usr/share/pegasus/sql/schema_tool.py -c connString=sqlite:///to/the/workflow/directory/with/
workflow.stampede.db
2012-02-29T01:29:43.330476Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.init |
2012-02-29T01:29:43.330708Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema.start |
2012-02-29T01:29:43.348995Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema
| Current version set to: 3.1.
2012-02-29T01:29:43.349133Z ERROR netlogger.analysis.schema.schema_check.SchemaCheck.check_schema
| Schema version 3.1 found - expecting 4.0 - database admin will
need to run upgrade tool.
```

Convert the Database to be version 4.x compliant

```
/usr/share/pegasus/sql/schema_tool.py -u connString=sqlite:///to/the/workflow/directory/with/
workflow.stampede.db
2012-02-29T01:35:35.046317Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.init |
2012-02-29T01:35:35.046554Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema.start |
```

Current version set to: 4.0.
2012-02-29T01:39:17.237624Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema |
Schema up to date.

```

For upgrading a MySQL database the steps remain the same. The only thing that changes is the connection String to the database
E.g.

```

/usr/share/pegasus/sql/schema_tool.py -u connString=mysql://username:password@server:port/dbname

```

After the database has been upgraded you can use either 3.x or 4.x clients to query the database with **pegasus-statistics**, as well as **pegasus-plots** and **pegasus-analyzer**.

Storing of Exitcode in the database

Kickstart records capture raw status in addition to the exitcode. The exitcode is derived from the raw status. Starting with Pegasus 4.0 release, all exitcode columns (i.e invocation and job instance table columns) are stored with the raw status by pegasus-monitor. If an exitcode is encountered while parsing the dagman log files , the value is converted to the corresponding raw status before it is stored. All user tools, pegasus-analyzer and pegasus-statistics then convert the raw status to exitcode when retrieving from the database.

Multiplier Factor

Starting with the 4.0 release, there is a multiplier factor associated with the jobs in the job_instance table. It defaults to one, unless the user associates a Pegasus profile key named **cores** with the job in the DAX. The factor can be used for getting more accurate statistics for jobs that run on multiple processors/cores or mpi jobs.

The multiplier factor is used for computing the following metrics by pegasus statistics.

- In the summary, the workflow cumulative job walltime
- In the summary, the cumulative job walltime as seen from the submit side
- In the jobs file, the multiplier factor is listed along-with the multiplied kickstart time.
- In the breakdown file, where statistics are listed per transformation the mean, min , max and average values take into account the multiplier factor.

API Reference

DAX XML Schema

The DAX format is described by the XML schema instance document dax-3.3.xsd [<http://pegasus.isi.edu/wms/docs/schemas/dax-3.3/dax-3.3.xsd>]. A local copy of the schema definition is provided in the “etc” directory. The documentation of the XML schema and its elements can be found in dax-3.3.html [<http://pegasus.isi.edu/wms/docs/schemas/dax-3.3/dax-3.3.html>] as well as locally in doc/schemas/dax-3.3/dax-3.3.html in your Pegasus distribution.

DAX XML Schema In Detail

The DAX file format has four major sections, with the second section divided into more sub-sections. The DAX format works on the abstract or logical level, letting you focus on the shape of the workflows, what to do and what to work upon.

1. Workflow-level Notifications

Very simple workflow-level notifications. These are defined in the Notification section.

2. Catalogs

The first section deals with included catalogs. While we do recommend to use external replica- and transformation catalogs, it is possible to include some replicas and transformations into the DAX file itself. Any DAX-included entry takes precedence over regular replica catalog (RC) and transformation catalog (TC) entries.

The first section (and any of its sub-sections) is completely optional.

- a. The first sub-section deals with included replica descriptions.
- b. The second sub-section deals with included transformation descriptions.
- c. The third sub-section declares multi-item executables.

3. Job List

The jobs section defines the job- or task descriptions. For each task to conduct, a three-part logical name declares the task and aides identifying it in the transformation catalog or one of the *executable* section above. During planning, the logical name is translated into the physical executable location on the chosen target site. By declaring jobs abstractly, physical layout consideration of the target sites do not matter. The job's *id* uniquely identifies the job within this workflow.

The arguments declare what command-line arguments to pass to the job. If you are passing filenames, you should refer to the logical filename using the *file* element in the argument list.

Important for properly planning the task is the list of files consumed by the task, its input files, and the files produced by the task, its output files. Each file is described with a *uses* element inside the task.

Elements exist to link a logical file to any of the stdio file descriptors. The *profile* element is Pegasus's way to abstract site-specific data.

Jobs are nodes in the workflow graph. Other nodes include unplanned workflows (DAX), which are planned and then run when the node runs, and planned workflows (DAG), which are simply executed.

4. Control-flow Dependencies

The third section lists the dependencies between the tasks. The relationships are defined as child parent relationships, and thus impacts the order in which tasks are run. No cyclic dependencies are permitted.

Dependencies are directed edges in the workflow graph.

XML Intro

If you have seen the DAX schema before, not a lot of new items in the root element. *However*, we did retire the (old) attributes ending in *Count*.

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- generated: 2011-07-28T18:29:57Z -->
<adag xmlns="http://pegasus.isi.edu/schema/DAX"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://pegasus.isi.edu/schema/DAX http://pegasus.isi.edu/schema/
dax-3.3.xsd"
      version="3.3"
      name="diamond"
      index="0"
```

```
count="1">
```

The following attributes are supported for the root element *adag*.

Table 10.18.

attribute	optional?	type	meaning
version	required	<i>VersionPattern</i>	Version number of DAX instance document. Must be 3.3.
name	required	string	name of this DAX (or set of DAXes).
count	optional	positiveInteger	size of list of DAXes with this <i>name</i> . Defaults to 1.
index	optional	nonNegativeInteger	current index of DAX with same <i>name</i> . Defaults to 0.
fileCount	removed	nonNegativeInteger	Old 2.1 attribute, removed, do not use.
jobCount	removed	positiveInteger	Old 2.1 attribute, removed, do not use.
childCount	removed	nonNegativeInteger	Old 2.1 attribute, removed, do not use.

The *version* attribute is restricted to the regular expression `\d+(\.\d+(\.\d+)?)?`. This expression represents the *VersionPattern* type that is used in other places, too. It is a more restrictive expression than before, but allows us to compute comparable version number using the following formula:

version1: a.b.c	version2: d.e.f
$n = a * 1,000,000 + b * 1,000 + c$	$m = d * 1,000,000 + e * 1,000 + f$
version1 > version2 if $n > m$	

Workflow-level Notifications

(something to be said here.)

```
<!-- part 1.1: invocations -->
<invoke when="at_end">/bin/date -Ins %t;%t; my.log</invoke>
```

The above snippet will append the current time to a log file in the current directory. This is with regards to the monitored instance acting on the notification.

The Catalogs Section

The initial section features three sub-sections:

1. a catalog of files used,
2. a catalog of transformations used, and
3. compound transformation declarations.

The Replica Catalog Section

The file section acts as in in-file replica catalog (RC). Any files declared in this section take precedence over files in external replica catalogs during planning.

```
<!-- part 1.2: included replica catalog -->
<file name="example.a" >
  <!-- profiles are optional -->
```

```

<!-- The "stat" namespace is ONLY AN EXAMPLE -->
<profile namespace="stat" key="size">/* integer to be defined */</profile>
<profile namespace="stat" key="md5sum">/* 32 char hex string */</profile>
<profile namespace="stat" key="mtime">/* ISO-8601 timestamp */</profile>

<!-- metadata is currently NOT SUPPORTED -->
<metadata key="timestamp" type="int">/* ISO-8601 *or* 20100417134523:int */</metadata>
<metadata key="origin" type="string">ocean</metadata>

<!-- PFN to by-pass replica catalog -->
<!-- The "site" attribute is optional -->
<pfn url="file:///tmp/example.a" site="local">
  <profile namespace="stat" key="owner">voeckler</profile>
</pfn>
<pfn url="file:///storage/funky.a" site="local"/>
</file>

<!-- a more typical example from the black diamond -->
<file name="f.a">
  <pfn url="file:///Users/voeckler/f.a" site="local"/>
</file>

```

The first *file* entry above is an example of a data file with two replicas. The *file* element requires a logical file *name*. Each logical filename may have additional information associated with it, enumerated by *profile* elements. Each file entry may have 0 or more *metadata* associated with it. Each piece of metadata has a *key* string and *type* attribute describing the element's value.

Warning

The *metadata* element is not support as of this writing! Details may change in the future.

The *file* element can provide 0 or more *pfn* locations, taking precedence over the replica catalog. A *file* element that does not name any *pfn* children-elements will still require look-ups in external replica catalogs. Each *pfn* element names a concrete location of a file. Multiple locations constitute replicas of the same file, and are assumed to be usable interchangeably. The *url* attribute is mandatory, and typically would use a file schema URL. The *site* attribute is optional, and defaults to value *local* if missing. A *pfn* element may have *profile* children-elements, which refer to attributes of the physical file. The file-level profiles refer to attributes of the logical file.

Note

The *stat* profile namespace is only an example, and details about *stat* are not yet implemented. The proper namespaces *pegasus*, *condor*, *dagman*, *env*, *hints*, *globus* and *selector* enjoy full support.

The second *file* entry above shows a usage example from the black-diamond example workflow that you are more likely to encounter or write.

The presence of an in-file replica catalog lets you declare a couple of interesting advanced features. The DAG and DAX file declarations are just files for all practical purposes. For deferred planning, the location of the site catalog (SC) can be captured in a file, too, that is passed to the job dealing with the deferred planning as logical filename.

```

<file name="black.dax" >
  <!-- specify the location of the DAX file -->
  <pfn url="file:///Users/vahi/Pegasus/work/dax-3.0/blackdiamond_dax.xml" site="local"/>
</file>

<file name="black.dag" >
  <!-- specify the location of the DAG file -->
  <pfn url="file:///Users/vahi/Pegasus/work/dax-3.0/blackdiamond.dag" site="local"/>
</file>

<file name="sites.xml" >
  <!-- specify the location of a site catalog to use for deferred planning -->
  <pfn url="file:///Users/vahi/Pegasus/work/dax-3.0/conf/sites.xml" site="local"/>
</file>

```

The Transformation Catalog Section

The executable section acts as an in-file transformation catalog (TC). Any transformations declared in this section take precedence over the external transformation catalog during planning.

```

<!-- part 1.3: included transformation catalog -->
<executable namespace="example" name="mDiffFit" version="1.0"
  arch="x86_64" os="linux" installed="true" >
  <!-- profiles are optional -->
  <!-- The "stat" namespace is ONLY AN EXAMPLE! -->
  <profile namespace="stat" key="size">5000</profile>
  <profile namespace="stat" key="md5sum">AB454DSSDA4646DS</profile>
  <profile namespace="stat" key="mtime">2010-11-22T10:05:55.470606000-0800</profile>

  <!-- metadata is currently NOT SUPPORTED! -->
  <metadata key="timestamp" type="int"/* see above */</metadata>
  <metadata key="origin" type="string">ocean</metadata>

  <!-- PFN to by-pass transformation catalog -->
  <!-- The "site" attribute is optional -->
  <pfn url="file:///tmp/mDiffFit" site="local"/>
  <pfn url="file:///tmp/storage/mDiffFit" site="local"/>
</executable>

<!-- to be used in compound transformation later -->
<executable namespace="example" name="mDiff" version="1.0"
  arch="x86_64" os="linux" installed="true" >
  <pfn url="file:///tmp/mDiff" site="local"/>
</executable>

<!-- to be used in compound transformation later -->
<executable namespace="example" name="mFitplane" version="1.0"
  arch="x86_64" os="linux" installed="true" >
  <pfn url="file:///tmp/mDiffFitplane" site="local">
    <profile namespace="stat" key="md5sum">0a9c38b919c7809cb645fc09011588a6</profile>
  </pfn>
  <invoke when="at_end">/path/to/my_send_email some args</invoke>
</executable>

<!-- a more likely example from the black diamond -->
<executable namespace="diamond" name="preprocess" version="2.0"
  arch="x86_64"
  os="linux"
  osversion="2.6.18">
  <pfn url="file:///opt/pegasus/default/bin/keg" site="local" />
</executable>

```

Logical filenames pertaining to a single executables in the transformation catalog use the *executable* element. Any *executable* element features the optional *namespace* attribute, a mandatory *name* attribute, and an optional *version* attribute. The *version* attribute defaults to "1.0" when absent. An executable typically needs additional attributes to describe it properly, like the architecture, OS release and other flags typically seen with transformations, or found in the transformation catalog.

Table 10.19.

attribute	optional?	type	meaning
name	required	string	logical transformation name
namespace	optional	string	namespace of logical transformation, default to <i>null</i> value.
version	optional	VersionPattern	version of logical transformation, defaults to "1.0".
installed	optional	boolean	whether to stage the file (false), or not (true, default).
arch	optional	Architecture	restricted set of tokens, see schema definition file.
os	optional	OSType	restricted set of tokens, see schema definition file.
osversion	optional	VersionPattern	kernel version as beginning of <code>`uname -r`</code> .
glibc	optional	VersionPattern	version of libc.

The rationale for giving these flags in the *executable* element header is that PFNs are just identical replicas or instances of a given LFN. If you need a different 32/64 bit-ness or OS release, the underlying PFN would be different, and thus the LFN for it should be different, too.

Note

We are still discussing some details and implications of this decision.

The initial examples come with the same caveats as for the included replica catalog.

Warning

The *metadata* element is not support as of this writing! Details may change in the future.

Similar to the replica catalog, each *executable* element may have 0 or more *profile* elements abstracting away site-specific details, zero or more *metadata* elements, and zero or more *pfn* elements. If there are no *pfn* elements, the transformation must still be searched for in the external transformation catalog. As before, the *pfn* element may have *profile* children-elements, referring to attributes of the physical filename itself.

Each *executable* element may also feature *invoke* elements. These enable notifications at the appropriate point when every job that uses this executable reaches the point of notification. Please refer to the notification section for details and caveats.

The last example above comes from the black diamond example workflow, and presents the kind and extend of attributes you are most likely to see and use in your own workflows.

The Compound Transformation Section

The compound transformation section declares a transformation that comprises multiple plain transformation. You can think of a compound transformation like a script interpreter and the script itself. In order to properly run the application, you must start both, the script interpreter and the script passed to it. The compound transformation helps Pegasus to properly deal with this case, especially when it needs to stage executables.

```
<transformation namespace="example" version="1.0" name="mDiffFit" >
  <uses name="mDiffFit" />
  <uses name="mDiff" namespace="example" version="2.0" />
  <uses name="mFitPlane" />
  <uses name="mDiffFit.config" executable="false" />
</transformation>
```

A *transformation* element declares a set of purely logical entities, executables and config (data) files, that are all required together for the same job. Being purely logical entities, the lookup happens only when the transformation element is referenced (or instantiated) by a job element later on.

The *namespace* and *version* attributes of the transformation element are optional, and provide the defaults for the inner uses elements. They are also essential for matching the transformation with a job.

The *transformation* is made up of 1 or more *uses* element. Each *uses* has a boolean attribute *executable*, *true* by default, or *false* to indicate a data file. The *name* is a mandatory attribute, referring to an LFN declared previously in the File Catalog (*executable* is *false*), Executable Catalog (*executable* is *true*), or to be looked up as necessary at instantiation time. The lookup catalog is determined by the *executable* attribute.

After *uses* elements, any number of *invoke* elements may occur to add a notification each whenever this transformation is instantiated.

The *namespace* and *version* attributes' default values inside *uses* elements are inherited from the *transformation* attributes of the same name. There is no such inheritance for *uses* elements with *executable* attribute of *false*.

Graph Nodes

The nodes in the DAX comprise regular job nodes, already instantiated sub-workflows as dag nodes, and still to be instantiated dax nodes. Each of the graph nodes can has a mandatory *id* attribute. The *id* attribute is currently a

restriction of type *NodeIdentifierPattern* type, which is a restriction of the `xs:NMTOKEN` type to letters, digits, hyphen and underscore.

The *level* attribute is deprecated, as the planner will trust its own re-computation more than user input. Please do not use nor produce any *level* attribute.

The *node-label* attribute is optional. It applies to the use-case when every transformation has the same name, but its arguments determine what it really does. In the presence of a *node-label* value, a workflow grapher could use the label value to show graph nodes to the user. It may also come in handy while debugging.

Any job-like graph node has the following set of children elements, as defined in the *AbstractJobType* declaration in the schema definition:

- 0 or 1 *argument* element to declare the command-line of the job's invocation.
- 0 or more *profile* elements to abstract away site-specific or job-specific details.
- 0 or 1 *stdin* element to link a logical file the the job's standard input.
- 0 or 1 *stdout* element to link a logical file to the job's standard output.
- 0 or 1 *stderr* element to link a logical file to the job's standard error.
- 0 or more *uses* elements to declare consumed data files and produced data files.
- 0 or more *invoke* elements to solicit notifications whence a job reaches a certain state in its life-cycle.

Job Nodes

A job element has a number of attributes. In addition to the *id* and *node-label* described in (Graph Nodes)above, the optional *namespace*, mandatory *name* and optional *version* identify the transformation, and provide the look-up handle: first in the DAX's *transformation* elements, then in the *executable* elements, and finally in an external transformation catalog.

```
<!-- part 2: definition of all jobs (at least one) -->
<job id="ID000001" namespace="example" name="mDiffFit" version="1.0"
  node-label="preprocess" >
  <argument>-a top -T 6 -i <file name="f.a"/> -o <file name="f.b1"/></argument>

  <!-- profiles are optional -->
  <profile namespace="execution" key="site">isi_viz</profile>
  <profile namespace="condor" key="getenv">>true</profile>

  <uses name="f.a" link="input" register="false" transfer="true" type="data" />
  <uses name="f.b" link="output" register="false" transfer="true" type="data" />

  <!-- 'WHEN' enumeration: never, start, on_error, on_success, on_end, all -->
  <!-- PEGASUS_* env-vars: event, status, submit dir, wf/job id, stdout, stderr -->
  <invoke when="start">/path/to arg arg</invoke>
  <invoke when="on_success"><![CDATA[/path/to arg arg]]></invoke>
  <invoke when="on_end"><![CDATA[/path/to arg arg]]></invoke>
</job>
```

The *argument* element contains the complete command-line that is needed to invoke the executable. The only variable components are logical filenames, as included *file* elements.

The *profile* argument lets you encapsulate site-specific knowledge .

The *stdin*, *stdout* and *stderr* element permits you to connect a stdio file descriptor to a logical filename. Note that you will still have to declare these files in the *uses* section below.

The *uses* element enumerates all the files that the task consumes or produces. While it is not necessary nor required to have all files appear on the command-line, it is imperative that you declare even hidden files that your task requires in this section, so that the proper ancilliary staging- and clean-up tasks can be generated during planning.

The *invoke* element may be specified multiple times, as needed. It has a mandatory when attribute with the following value set:

Table 10.20.

keyword	job life-cycle state	meaning
never	never	(default). Never notify of anything. This is useful to temporarily disable an existing notifications.
start	submit	create a notification when the job is submitted.
on_error	end	after a job finishes with failure (exit-code != 0).
on_success	end	after a job finishes with success (exit-code == 0).
at_end	end	after a job finishes, regardless of exit-code.
all	always	like start and at_end combined.

Warning

In clustered jobs, a notification can only be sent at the start or end of the clustered job, not for each member.

Each *invoke* is a simple local invocation of an executable or script with the specified arguments. The executable inside the invoke body will see the following environment variables:

Table 10.21.

variable	job life-cycle state	meaning
PEGASUS_EVENT	always	The value of the when attribute
PEGASUS_STATUS	end	The exit status of the graph node. Only available for end notifications.
PEGASUS_SUBMIT_DIR	always	In which directory to find the job (or workflow).
PEGASUS_JOBID	always	The job (or workflow) identifier. This is potentially more than merely the value of the <i>id</i> attribute.
PEGASUS_STDOUT	always	The filename where <i>stdout</i> goes. Empty and possibly non-existent at submit time (though we still have the filename). The kickstart record for job nodes.
PEGASUS_STDERR	always	The filename where <i>stderr</i> goes. Empty and possibly non-existent at submit time (though we still have the filename).

Generators should use CDATA encapsulated values to the invoke element to minimize interference. Unfortunately, CDATA cannot be nested, so if the user invocation contains a CDATA section, we suggest that they use careful XML-entity escaped strings. The notifications section describes these in further detail.

DAG Nodes

A workflow that has already been concretized, either by an earlier run of Pegasus, or otherwise constructed for DAG-Man execution, can be included into the current workflow using the *dag* element.

```
<dag id="ID000003" name="black.dag" node-label="foo" >
  <profile namespace="dagman" key="DIR"/>dag-dir/test</profile>
```

```

    <invoke> <!-- optional, should be possible --> </invoke>
    <uses file="sites.xml" link="input" register="false" transfer="true" type="data"/>
  </dag>

```

The *id* and *node-label* attributes were described previously. The *name* attribute refers to a file from the File Catalog that provides the actual DAGMan DAG as data content. The *dag* element features optional *profile* elements. These would most likely pertain to the *dagman* and *env* profile namespaces. It should be possible to have the optional *notify* element in the same manner as for jobs.

A graph node that is a *dag* instead of a job would just use a different submit file generator to create a DAGMan invocation. There can be an *argument* element to modify the command-line passed to DAGMan.

DAX Nodes

A still to be planned workflow incurs an invocation of the Pegasus planner as part of the workflow. This still abstract sub-workflow uses the *dax* element.

```

<dax id="ID000002" name="black.dax" node-label="bar" >
  <profile namespace="env" key="foo">bar</profile>
  <argument>-Xmx1024 -Xms512 -Dpegasus.dir.storage=storagedir -Dpegasus.dir.exec=execdir -o local
--dir ./datafind -vvvvv --force -s dax_site </argument>
  <invoke> <!-- optional, may not be possible here --> </invoke>
  <uses file="sites.xml" link="input" register="false" transfer="true" type="data" />
</dax>

```

In addition to the *id* and *node-label* attributes, See Graph Nodes. The *name* attribute refers to a file from the File Catalog that provides the to be planned DAX as external file data content. The *dax* element features optional *profile* elements. These would most likely pertain to the *pegasus*, *dagman* and *env* profile namespaces. It may be possible to have the optional *notify* element in the same manner as for jobs.

A graph node that is a *dax* instead of a job would just use yet another submit file and pre-script generator to create a DAGMan invocation. The *argument* string pertains to the command line of the to-be-generated DAGMan invocation.

Inner ADAG Nodes

While completeness would argue to have a recursive nesting of *adag* elements, such recursive nestings are currently not supported, not even in the schema. If you need to nest workflows, please use the *dax* or *dag* element to achieve the same goal.

The Dependency Section

This section describes the dependencies between the jobs.

```

<!-- part 3: list of control-flow dependencies -->
<child ref="ID000002">
  <parent ref="ID000001" edge-label="edge1" />
</child>
<child ref="ID000003">
  <parent ref="ID000001" edge-label="edge2" />
</child>
<child ref="ID000004">
  <parent ref="ID000002" edge-label="edge3" />
  <parent ref="ID000003" edge-label="edge4" />
</child>

```

Each *child* element contains one or more *parent* element. Either element refers to a *job*, *dag* or *dax* element id attribute using the *ref* attribute. In this version, we relaxed the `xs:IDREF` constraint in favor of a restriction on the `xs:NMTOKEN` type to permit a larger set of identifiers.

The *parent* element has an optional *edge-label* attribute.

Warning

The *edge-label* attribute is currently unused.

Its goal is to annotate edges when drawing workflow graphs.

Closing

As any XML element, the root element needs to be closed.

```
</adag>
```

DAX XML Schema Example

The following code example shows the XML instance document representing the diamond workflow.

```
<?xml version="1.0" encoding="UTF-8"?>
<adag xmlns="http://pegasus.isi.edu/schema/DAX"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://pegasus.isi.edu/schema/DAX http://pegasus.isi.edu/schema/dax-3.3.xsd"
version="3.3" name="diamond" index="0" count="1">
  <!-- part 1.1: invocations -->
  <invoke when="on_error">/bin/mailx -s &apos;diamond failed&apos; use@some.domain</invoke>

  <!-- part 1.2: included replica catalog -->
  <file name="f.a">
    <pfn url="file:///lfs/voeckler/src/svn/pegasus/trunk/examples/grid-blackdiamond-perl/f.a"
site="local" />
  </file>

  <child ref="ID000003">
```

```
<parent ref="ID000001" />
</child>
<child ref="ID000004">
  <parent ref="ID000002" />
  <parent ref="ID000003" />
</child>
</adag>
```

The above workflow defines the black diamond from the abstract workflow section of the Introduction chapter. It will require minimal configuration, because the catalog sections include all necessary declarations.

The file element defines the location of the required input file in terms of the local machine. Please note that

- The **file** element declares the required input file "f.a" in terms of the local machine. Please note that if you plan the workflow for a remote site, there has to be some way for the file to be staged from the local site to the remote site. While Pegasus will augment the workflow with such ancillary jobs, the site catalog as well as local and remote site have to be set up properly. For a locally run workflow you don't need to do anything.
- The **executable** elements declare the same executable key that is to be run for each the logical transformation in terms of the remote site *futuregrid*. To declare it for a local site, you would have to adjust the *site* attribute's value to *local*. This section also shows that the same executable may come in different guises as transformation.
- The **job** elements define the workflow's logical constituents, the way to invoke the `key` command, where to put filenames on the commandline, and what files are consumed or produced. In addition to the direction of files, further attributes determine whether to register the file with a replica catalog and whether to transfer it to the output site in case of a product. We are only interested in the final data product "f.d" in this workflow, and not any intermediary files. Typically, you would also want to register the data products in the replica catalog, especially in larger scenarios.
- The **child** elements define the control flow between the jobs.

DAX Generator API

The DAX generating APIs support Java, Perl and Python. This section will show in each language the necessary code, using Pegasus-provided libraries, to generate the diamond DAX example above. There may be minor differences in details, e.g. to show-case certain features, but effectively all generate the same basic diamond.

The Java DAX Generator API

The Java DAX API provided with the Pegasus distribution allows easy creation of complex and huge workflows. This API is used by several applications to generate their abstract DAX. SCEC, which is Southern California Earthquake Center, uses this API in their CyberShake workflow generator to generate huge DAX containing 10's of thousands of tasks with 100's of thousands of input and output files. The Java API [javadoc/index.html] is well documented using Javadoc for ADAGs [javadoc/edu/isi/pegasus/planner/dax/ADAG.html] .

The steps involved in creating a DAX using the API are

1. Create a new *ADAG* object
2. Add any Workflow notification elements
3. Create *File* objects as necessary. You can augment the files with physical information, if you want to include them into your DAX. Otherwise, the physical information is determined from the replica catalog.
4. (Optional) Create *Executable* objects, if you want to include your transformation catalog into your DAX. Otherwise, the translation of a job/task into executable location happens with the transformation catalog.
5. Create a new *Job* object.
6. Add arguments, files, profiles, notifications and other information to the *Job* object
7. Add the job object to the *ADAG* object
8. Repeat step 4-6 as necessary.
9. Add all dependencies to the *ADAG* object.

10. Call the *writeToFile()* method on the *ADAG* object to render the XML DAX file.

An example Java code that generates the diamond dax show above is listed below. This same code can be found in the Pegasus distribution in the `examples/grid-blackdiamond-java` directory as `BlackDiamondDAX.java`:

```

        dax.addDependency("j3", "j4");
        return dax;
    }

    /**
     * Create an example DIAMOND DAX
     * @param args
     */
    public static void main(String[] args) {
        if (args.length != 1) {
            System.out.println("Usage: java GenerateDiamondDAX <pegasus_location> ");
            System.exit(1);
        }

        try {
            Diamond diamond = new Diamond();
            String pegasusHome = args[0];
            String site = "TestCluster";
            ADAG dag = diamond.generate( site, pegasusHome );
            dag.writeToSTDOUT();
            //generate(args[0], args[1]).writeToFile(args[2]);
        }
        catch (Exception e) {
            e.printStackTrace();
        }
    }
}

```

```
}

```

Of course, you will have to set up some catalogs and properties to run this example. The details are captured in the examples directory `examples/grid-blackdiamond-java`.

The Python DAX Generator API

Refer to the auto-generated python documentation [python/] explaining this API.

```
#!/usr/bin/env python

from Pegasus.DAX3 import *
import sys
import os

if len(sys.argv) != 2:
    print "Usage: %s PEGASUS_HOME" % (sys.argv[0])
    sys.exit(1)

# Create a abstract dag
diamond = ADAG("diamond")

# Add input file to the DAX-level replica catalog
a = File("f.a")
a.addPFN(PFN("file://" + os.getcwd() + "/f.a", "local"))
diamond.addFile(a)

# Add executables to the DAX-level replica catalog
# In this case the binary is keg, which is shipped with Pegasus, so we use
# the remote PEGASUS_HOME to build the path.
e_preprocess = Executable(namespace="diamond", name="preprocess", version="4.0", os="linux",
    arch="x86_64")
e_preprocess.addPFN(PFN("file://" + sys.argv[1] + "/bin/keg", "TestCluster"))
diamond.addExecutable(e_preprocess)

e_findrange = Executable(namespace="diamond", name="findrange", version="4.0", os="linux",
    arch="x86_64")
e_findrange.addPFN(PFN("file://" + sys.argv[1] + "/bin/keg", "TestCluster"))
diamond.addExecutable(e_findrange)

e_analyze = Executable(namespace="diamond", name="analyze", version="4.0", os="linux",
    arch="x86_64")
e_analyze.addPFN(PFN("file://" + sys.argv[1] + "/bin/keg", "TestCluster"))
diamond.addExecutable(e_analyze)

# Add a preprocess job
preprocess = Job(namespace="diamond", name="preprocess", version="4.0")
b1 = File("f.b1")
b2 = File("f.b2")
preprocess.addArguments("-a preprocess", "-T60", "-i", a, "-o", b1, b2)
preprocess.uses(a, link=Link.INPUT)
preprocess.uses(b1, link=Link.OUTPUT)
preprocess.uses(b2, link=Link.OUTPUT)
diamond.addJob(preprocess)

# Add left Findrange job
frl = Job(namespace="diamond", name="findrange", version="4.0")
c1 = File("f.c1")
frl.addArguments("-a findrange", "-T60", "-i", b1, "-o", c1)
frl.uses(b1, link=Link.INPUT)
frl.uses(c1, link=Link.OUTPUT)
diamond.addJob(frl)

# Add right Findrange job
frr = Job(namespace="diamond", name="findrange", version="4.0")
c2 = File("f.c2")
frr.addArguments("-a findrange", "-T60", "-i", b2, "-o", c2)
frr.uses(b2, link=Link.INPUT)
frr.uses(c2, link=Link.OUTPUT)
diamond.addJob(frr)

# Add Analyze job
analyze = Job(namespace="diamond", name="analyze", version="4.0")
d = File("f.d")
analyze.addArguments("-a analyze", "-T60", "-i", c1, c2, "-o", d)
```

```

analyze.uses(c1, link=Link.INPUT)
analyze.uses(c2, link=Link.INPUT)
analyze.uses(d, link=Link.OUTPUT, register=True)
diamond.addJob(analyze)

# Add control-flow dependencies
diamond.depends(parent=preprocess, child=frr)
diamond.depends(parent=preprocess, child=frr)
diamond.depends(parent=frr, child=analyze)
diamond.depends(parent=frr, child=analyze)

# Add notification for analyze job
analyze.invoke(When.ON_ERROR, '/home/user/bin/email -s "Analyze job failed" user@example.com')

# Add notification for workflow
diamond.invoke(When.AT_END, '/home/user/bin/email -s "Workflow finished" user@example.com')
diamond.invoke(When.ON_SUCCESS, '/home/user/bin/publish_workflow_result')

# Write the DAX to stdout
diamond.writeXML(sys.stdout)

```

The Perl DAX Generator

The Perl API example below can be found in file `blackdiamond.pl` in directory `examples/grid-black-diamond-perl`. It requires that you set the environment variable `PEGASUS_HOME` to the installation directory of Pegasus, and include into `PERL5LIB` the path to the directory `lib/perl` of the Pegasus installation. The actual code is longer, and will not require these settings, only the example below does. The Perl API is documented using `perldoc` [<http://pegasus.isi.edu/wms/docs/3.0/perl/>]. For each of the modules you can invoke `perldoc`, if your `PERL5LIB` variable is set.

The steps to generate a DAX from Perl are similar to the Java steps. However, since most methods to the classes are deeply within the Perl class modules, the convenience module `Perl::DAX::Factory` makes most constructors accessible without you needing to type your fingers raw:

1. Create a new *ADAG* object.
2. Create *Job* objects as necessary.
3. As example, the required input file "f.a" is declared as *File* object and linked to the *ADAG* object.
4. The first job arguments and files are filled into the job, and the job is added to the *ADAG* object.
5. Repeat step 4 for the remaining jobs.
6. Add dependencies for all jobs. You have the option of assigning label text to edges, though these are not used (yet).
7. To generate the DAX file, invoke the `toXML()` method on the *ADAG* object. The first argument is an opened file handle or `IO::Handle` descriptor scalar to write to, the second the default indentation for the root element, and the third the XML namespace to use for elements and attributes. The latter is typically unused unless you want to include your output into another XML document.

```

#!/usr/bin/env perl
#
use 5.006;
use strict;
use IO::Handle;
use Cwd;
use File::Spec;
use File::Basename;
use Sys::Hostname;
use POSIX ();

BEGIN { $ENV{'PEGASUS_HOME'} ||= `pegasus-config --nocrlf --home` }
use lib File::Spec->catdir( $ENV{'PEGASUS_HOME'}, 'lib', 'perl' );

use Pegasus::DAX::Factory qw(:all);
use constant NS => 'diamond';

my $adag = newADAG( name => NS );
my $job1 = newJob( namespace => NS, name => 'preprocess', version => '2.0' );
my $job2 = newJob( namespace => NS, name => 'findrange', version => '2.0' );
my $job3 = newJob( namespace => NS, name => 'findrange', version => '2.0' );

```

```

my $job4 = newJob( namespace => NS, name => 'analyze', version => '2.0' );

# create "f.a" locally
my $fn = "f.a";
open( F, ">$fn" ) || die "FATAL: Unable to open $fn: $!\n";
my @now = gmtime();
printf F "%04u-%02u-%02u %02u:%02u:%02uZ\n",
        $now[5]+1900, $now[4]+1, @now[3,2,1,0];
close F;

my $file = newFile( name => 'f.a' );
$file->addPFN( newPFN( url => 'file://' . Cwd::abs_path($fn),
                    site => 'local' ) );
$dag->addFile($file);

# follow this path, if the PEGASUS_HOME was determined
if ( exists $ENV{'PEGASUS_HOME'} ) {
    my $keg = File::Spec->catfile( $ENV{'PEGASUS_HOME'}, 'bin', 'keg' );
    my @os = POSIX::uname();
    # $os[2] =~ s/^(\\d+(\\.\\d+(\\.\\d+)?)?.*)/$1/; ## create a proper osversion
    $os[4] =~ s/i.86/x86/;

    # add Executable instances to DAX-included TC. This will only work,
    # if we know how to access the keg executable. HOWEVER, for a grid
    # workflow, these entries are not used, and you need to
    # [1] install the work tools remotely
    # [2] create a TC with the proper entries
    if ( -x $keg ) {
        for my $j ( $job1, $job2, $job4 ) {
            my $app = newExecutable( namespace => $j->namespace,
                                    name => $j->name,
                                    version => $j->version,
                                    installed => 'false',
                                    arch => $os[4],
                                    os => lc($^O) );
            $app->addProfile( 'globus', 'maxtime', '2' );
            $app->addProfile( 'dagman', 'RETRY', '3' );
            $app->addPFN( newPFN( url => "file://$keg", site => 'local' ) );
            $dag->addExecutable($app);
        }
    }
}

my %hash = ( link => LINK_OUT, register => 'false', transfer => 'true' );

my $xmlns = shift;
$adag->toXML( \*STDOUT, '', $xmlns );
```

DAX Generator without a Pegasus DAX API

If you are using some other scripting or programming environment, you can directly write out the DAX format using the provided schema using any language. For instance, LIGO, the Laser Interferometer Gravitational Wave Observatory, generate their DAX files as XML using their own Python code, not using our provided API.

If you write your own XML, you *must* ensure that the generated XML is well formed and valid with respect to the DAX schema. You can use the **pegasus-dax-validator** to verify the validity of your generated file. Typically, you generate a smallish test file to, validate that your generator creates valid XML using the validator, and then ramp it up to produce the full workflow(s) you want to run. At this point the **pegasus-dax-validator** is a very simple program that will only take exactly one argument, the name of the file to check. The following snippet checks a black-diamond file that uses an improper *osversion* attribute in its *executable* element:

```
$ pegasus-dax-validator blackdiamond.dax
ERROR: cvc-pattern-valid: Value '2.6.18-194.26.1.el5' is not facet-valid
  with respect to pattern '[0-9]+(\.[0-9]+(\.[0-9]+)?)?' for type 'VersionPattern'.
ERROR: cvc-attribute.3: The value '2.6.18-194.26.1.el5' of attribute 'osversion'
  on element 'executable' is not valid with respect to its type, 'VersionPattern'.

0 warnings, 2 errors, and 0 fatal errors detected.
```

We are working on improving this program, e.g. provide output with regards to the line number where the issue occurred. However, it will return with a non-zero exit code whenever errors were detected.

Command Line Tools

Name

pegasus-analyzer — debugs a workflow.

Synopsis

```
pegasus-analyzer [--help|-h] [--quiet|-q] [--strict|-s]
                 [--monitord|-m|-t] [--verbose|-v]
                 [--output-dir|-o output_dir]
                 [--dag dag_filename] [--dir|-d|-i input_dir]
                 [--print|-p print_options] [--type workflow_type]
                 [--debug-job job][--debug-dir debug_dir]
                 [--local-executable local user executable]
                 [--conf|-c property_file] [--files]
                 [--top-dir dir_name] [workflow_directory]
```

Description

pegasus-analyzer is a command-line utility for parsing the *jobstate.log* file and reporting successful and failed jobs. When executed without any options, it will query the **SQLite** or **MySQL** database and retrieve failed job information for the particular workflow. When invoked with the **--files** option, it will retrieve information from several log files, isolating jobs that did not complete successfully, and printing their *stdout* and *stderr* so that users can get detailed information about their workflow runs.

Options

-h , --help	Prints a usage summary with all the available command-line options.
-q , --quiet	Only print the the output and error filenames instead of their contents.
-s , --strict	Get jobs' output and error filenames from the job's submit file.
-m , -t , --monitord	Invoke pegasus-monitord before analyzing the <i>jobstate.log</i> file. Although pegasus-analyzer can be executed during the workflow execution as well as after the workflow has already completed execution, pegasus-monitord is always invoked with the --replay option. Since multiple instances of pegasus-monitord should not be executed simultaneously in the same workflow directory, the user should ensure that no other instances of pegasus-monitord are running. If the <i>run_directory</i> is writable, pegasus-analyzer will create a <i>jobstate.log</i> file there, rotating an older log, if it is found. If the <i>run_directory</i> is not writable (e.g. when the user debugging the workflow is not the same user that ran the workflow), pegasus-analyzer will exit and ask the user to provide the --output-dir option, in order to provide an alternative location for pegasus-monitord log files.
-v , --verbose	Sets the log level for pegasus-analyzer . If omitted, the default <i>level</i> will be set to <i>WARNING</i> . When this option is given, the log level is changed to <i>INFO</i> . If this option is repeated, the log level will be changed to <i>DEBUG</i> .
-o output_dir , --output-dir output_dir	This option provides an alternative location for all monitoring log files for a particular workflow. It is mainly used when an user does not have write privileges to a workflow directory and needs to generate the log files needed by pegasus-analyzer . If this option is used in conjunction with the --monitord option, it will invoke pegasus-monitord using <i>output_dir</i> to store all output files. Because workflows can have sub-workflows, pegasus-monitord will create its files prepending the workflow <i>wf_uuid</i> to each filename. This way, multiple workflow files can be stored in the same directory. pegasus-analyzer has built-in logic to find the specific <i>jobstate.log</i> file by looking at the workflow <i>braindump.txt</i> file first and figuring out the corresponding <i>wf_uuid</i> . If <i>output_dir</i> does not exist, it will be created.

--dag <i>dag_filename</i>	In this option, <i>dag_filename</i> specifies the path to the <i>DAG</i> file to use. pegasus-analyzer will get the directory information from the <i>dag_filename</i> . This option overrides the --dir option below.
-d <i>input_dir</i> , -i <i>input_dir</i> , --dir <i>input_dir</i>	Makes pegasus-analyzer look for the <i>jobstate.log</i> file in the <i>input_dir</i> directory. If this option is omitted, pegasus-analyzer will look in the current directory.
-p <i>print_options</i> , --print <i>print_options</i>	Tells pegasus-analyzer what extra information it should print for failed jobs. <i>print_options</i> is a comma-delimited list of options, that include <i>pre</i> , <i>invocation</i> , and/or <i>all</i> , which activates all printing options. With the <i>pre</i> option, pegasus-analyzer will print the <i>pre-script</i> information for failed jobs. For the <i>invocation</i> option, pegasus-analyzer will print the <i>invocation</i> command, so users can manually run the failed job.
--debug-job <i>job</i>	When given this option, pegasus-analyzer turns on its <i>debug_mode</i> , when it can be used to debug a particular Pegasus Lite job. In this mode, pegasus-analyzer will create a shell script in the <i>debug_dir</i> (see below, for specifying it) and copy all necessary files to this local directory and then execute the job locally.
--debug-dir <i>debug_dir</i>	When in <i>debug_mode</i> , pegasus-analyzer will create a temporary debug directory. Users can give this option in order to specify a particular <i>debug_dir</i> directory to be used instead.
--local-executable <i>local user executable</i>	When in debug job mode for Pegasus Lite jobs, pegasus-analyzer creates a shell script to execute the Pegasus Lite job locally in a debug directory. The Pegasus Lite script refers to remote user executable path. This option can be used to pass the local path to the user executable on the submit host. If the path to the user executable in the Pegasus Lite job is same as the local installation.
--type <i>workflow_type</i>	In this options, users specify what <i>workflow_type</i> they want to debug. At this moment, the only <i>workflow_type</i> available is condor and it is the default value if this option is not specified.
-c <i>property_file</i> , --conf <i>property_file</i>	This option is used to specify an alternative property file, which may contain the path to the database to be used by pegasus-analyzer . If this option is not specified, the config file specified in the braindump.txt file will take precedence.
--files	This option allows users to run pegasus-analyzer using the files in the workflow directory instead of the database as the source of information. pegasus-analyzer will output the same information, this option only changes where the data comes from.
--top-dir <i>dir_name</i>	This option enables pegasus-analyzer to show information about sub-workflows when using the database mode. When debugging a top-level workflow with failures in sub-workflows, the analyzer will automatically print the command users should use to debug a failed sub-workflow. This allows the analyzer to find the database it needs to access.

Environment Variables

pegasus-analyzer does not require that any environmental variables be set. It locates its required Python modules based on its own location, and therefore should not be moved outside of Pegasus' bin directory.

Example

The simplest way to use **pegasus-analyzer** is to go to the *run_directory* and invoke the analyzer:

```
$ pegasus-analyzer .
```

which will cause **pegasus-analyzer** to print information about the workflow in the current directory.

pegasus-analyzer output contains a summary, followed by detailed information about each job that either failed, or is in an unknown state. Here is the summary section of the output:

```
*****Summary*****
```

```
Total jobs      :      75 (100.00%)
# jobs succeeded :      41 (54.67%)
# jobs failed    :        0 (0.00%)
# jobs unsubmitted :     33 (44.00%)
# jobs unknown   :        1 (1.33%)
```

jobs_succeeded are jobs that have completed successfully. *jobs_failed* are jobs that have finished, but that did not complete successfully. *jobs_unsubmitted* are jobs that are listed in the *dag_file*, but no information about them was found in the *jobstate.log* file. Finally, *jobs_unknown* are jobs that have started, but have not reached completion.

After the summary section, **pegasus-analyzer** will display information about each job in the *job_failed* and *job_unknown* categories.

```
*****Failed jobs' details*****
```

```
=====findrange_j3=====
```

```
last state: POST_SCRIPT_FAILURE
site: local
submit file: /home/user/diamond-submit/findrange_j3.sub
output file: /home/user/diamond-submit/findrange_j3.out.000
error file: /home/user/diamond-submit/findrange_j3.err.000
```

```
-----Task #1 - Summary-----
```

```
site      : local
hostname  : server-machine.domain.com
executable: (null)
arguments : -a findrange -T 60 -i f.b2 -o f.c2
error     : 2
working dir :
```

In the example above, the *findrange_j3* job has failed, and the analyzer displays information about the job, showing that the job finished with a *POST_SCRIPT_FAILURE*, and lists the *submit*, *output* and *error* files for this job. Whenever **pegasus-analyzer** detects that the output file contains a kickstart record, it will display the breakdown containing each task in the job (in this case we only have one task). Because **pegasus-analyzer** was not invoked with the **--quiet** flag, it will also display the contents of the *output* and *error* files (or the stdout and stderr sections of the kickstart record), which in this case are both empty.

In the case of *SUBDAG* and *subdax* jobs, **pegasus-analyzer** will indicate it, and show the command needed for the user to debug that sub-workflow. For example:

```
=====subdax_black_ID000009=====
```

```
last state: JOB_FAILURE
site: local
submit file: /home/user/run1/subdax_black_ID000009.sub
output file: /home/user/run1/subdax_black_ID000009.out
error file: /home/user/run1/subdax_black_ID000009.err
This job contains sub workflows!
Please run the command below for more information:
pegasus-analyzer -d /home/user/run1/blackdiamond_ID000009.000
```

```
-----subdax_black_ID000009.out-----
```

```
Executing condor dagman ...
```

```
-----subdax_black_ID000009.err-----
```

tells the user the *subdax_black_ID000009* sub-workflow failed, and that it can be debugged by using the indicated **pegasus-analyzer** command.

Authors

Fabio Silva <fabio at isi dot edu>

Karan Vahi <vahi at isi dot edu>

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-archive — Compresses a workflow submit directory in a way that allows **pegasus-dashboard**, **pegasus-statistics**, **pegasus-plots**, and **pegasus-analyzer** to keep working.

Synopsis

pegasus-archive [-h][-v][-x] *submit_dir*

Description

pegasus-archive significantly reduces the size of workflow submit directories by compressing the data in a way such that it remains accessible to tools such as **pegasus-statistics**, **pegasus-plots**, and **pegasus-analyzer**. It creates a `.tar.gz` archive of the submit files and logs that excludes files such as the stampede database, `braindump` file, and `monitord` logs, which are used by **pegasus** reporting tools.

Options

- | | |
|-----------------------|--|
| -h , --help | Prints a usage summary with all the available command-line options. |
| -v , --verbose | Print detailed messages about the archiving process. |
| -x , --extract | Un-archive a previously archived submit directory. This option returns the submit directory to the state it was before pegasus-archive was applied to it. |

Authors

Gideon Juve <gideon@isi.edu [<mailto:gideon@isi.edu>]>

Pegasus Team <http://pegasus.isi.edu>

Name

`pegasus-cleanup` — Removes files during Pegasus workflows enactment.

Synopsis

`pegasus-cleanup [-h][-l level][-f urls]`

Description

pegasus-cleanup removes the files associated with the given URL. Some of the protocols it can handle are GridFTP, SRM, Amazon S3, HTTP, and file://.

Options

-h , --help	Prints a usage summary with all the available command-line options.
-l level , --loglevel level	The debugging output level. Valid values are <i>debug</i> , <i>info</i> , <i>warning</i> , and <i>error</i> . Default value is <i>info</i> .
-f urls , --file urls	Specifies the file with URLs to clean up (one per line). If this option is not given the list of URLs will be read from stdin.

Example

```
echo gsiftp://somehost/some/path | pegasus-cleanup
```

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-cluster — run a list of applications

Synopsis

pegasus-cluster [-d] [-e | -f] [-S ec] [-s fn] [-R fn] [-n nr] [inputfile]

Description

The **pegasus-cluster** tool executes a list of application in the order specified (assuming sequential mode.) It is generally used to do horizontal clustering of independent application, and does not care about any application failures. Such failures should be caught by using **pegasus-kickstart** to start application.

In vertical clustering mode, the *hard failure* mode is encouraged, ending execution as soon as one application fails. When running a complex workflow through **pegasus-cluster**, the order of applications in the input file must be topologically sorted.

Applications are usually using **pegasus-kickstart** to execute. In the **pegasus-kickstart** case, all invocations of **pegasus-kickstart** except the first should add the **pegasus-kickstart** option *-H* to suppress repeating the XML preamble and certain other headers of no interest when repeated.

pegasus-cluster permits shell-style quoting. One level of quoting is removed from the arguments. Please note that **pegasus-kickstart** will also remove one level of quoting.

Arguments

- | | |
|--------------|--|
| -d | This option increases the debug level. Debug message are generated on <i>stdout</i> . By default, debugging is minimal. |
| -e | This flag turns on the old behavior of pegasus-cluster to always run everything <i>and</i> return success no matter what. The -e flag is mutually exclusive with the -f flag. By default, all applications are executed regardless of failures. Any detected application failure results in a non-zero exit status from pegasus-cluster . |
| -f | In hard failure mode, as soon as one application fails, either through a non-zero exit code, or by dying on a signal, further execution is stopped. In parallel execution mode, one or more other applications later in the sequence file may have been started already by the time failure is detected. Pegasus-cluster will wait for the completion of these applications, but not start new ones. The -f flag is mutually exclusive with the -e flag. By default, all applications are executed regardless of failures. Any detected application failure results in a non-zero exit status from pegasus-cluster . |
| -h | This option prints the help message and exits the program. |
| -s fn | This option will send protocol message (for Mei) to the specified file. By default, all message are written to <i>stdout</i> . |
| -R fn | The progress reporting feature, if turned on, will write one event record whenever an application is started, and one event record whenever an application finished. This is to enable tracking of jobs in progress. By default, track logs are not written, unless the environment variable <i>SEQEXEC_PROGRESS_REPORT</i> is set. If set, progress reports are appended to the file pointed to by the environment variable. |
| -S ec | This option is a multi-option, which may be used multiple times. For each given non-zero exit-code of an application, mark it as a form of success. In -f mode, this means that pegasus-cluster will not fail when seeing this exit code from any application it runs. By default, all non-zero exit code constitute failure. |
| -n nr | This option determines the amount of parallel execution. Typically, parallel execution is only recommended on multi-core systems, and must be deployed rather carefully, i.e. only completely independent jobs across of whole <i>inputfile</i> should ever be attempted to be run in parallel. The argu- |

ment **nr** is the number of parallel jobs that should be used. In addition to a non-negative integer, the word *auto* is also understood. When *auto* is specified, **pegasus-cluster** will attempt to automatically determine the number of cores available in the system. Strictly sequential execution, as if *nr* was 1, is the default. If the environment variable *SEQEXEC_CPUS* is set, it will determine the default number of CPUs.

inputfile The input file specifies a list of application to run, one per line. Comments and empty lines are permitted. The comment character is the octothorpe (#), and extends to the end of line. By default, **pegasus-cluster** uses *stdin* to read the list of applications to execute.

Return Value

The **pegasus-cluster** tool returns 1, if an illegal option was used. It returns 2, if the status file from option **-s** cannot be opened. It returns 3, if the input file cannot be opened. It does *not* return any failure for failed applications in old-exit **-e** mode. In *default* and hard failure **-f** mode, it will return 5 for true failure. The determination of failure is modified by the **-S** option.

All other internal errors being absent, **pegasus-cluster** will always return 0 when run without **-f**. Unlike shell, it will *not* return the last application's exit code. In *default* mode, it will return 5, if any application failed. Unlike shell, it will *not* return the last application's exit code. However, it will execute all applications. The determination of failure is modified by the **-S** flag. In **-f** mode, **pegasus-cluster** returns either 0 if all main sequence applications succeeded, or 5 if one failed; or more than one in parallel execution mode. It will run only as long as applications were successful. As before, the **-S** flag determines what constitutes a failure.

The **pegasus-cluster** application will also create a small summary on *stdout* for each job, and one for itself, about the success and failure. The field **failed** reports any exit code that was not zero or a signal of death termination. It does *not* include non-zero exit codes that were marked as success using the **-S** option.

Task Summary

Each task executed by **pegasus-cluster** generates a record bracketed by square brackets like this (each entry is broken over two lines for readability):

```
[cluster-task id=1, start="2011-04-27T14:31:25.340-07:00", duration=0.521,
 status=0, line=1, pid=18543, app="/bin/usleep"]
[cluster-task id=2, start="2011-04-27T14:31:25.342-07:00", duration=0.619,
 status=0, line=2, pid=18544, app="/bin/usleep"]
[cluster-task id=3, start="2011-04-27T14:31:25.862-07:00", duration=0.619,
 status=0, line=3, pid=18549, app="/bin/usleep"]
```

Each record is introduced by the string *cluster-task* with the following constituents, where strings are quoted:

id	This is a numerical value for main sequence application, indicating the application's place in the sequence file. The setup task uses the string <i>setup</i> , and the cleanup task uses the string <i>cleanup</i> .
start	is the ISO 8601 time stamp, with millisecond resolution, when the application was started. This string is quoted.
duration	is the application wall-time duration in seconds, with millisecond resolution.
status	is the <i>raw</i> exit status as returned by the <i>wait</i> family of system calls. Typically, the exit code is found in the high byte, and the signal of death in the low byte. Typically, 0 indicates a successful execution, and any other value a problem. However, details could differ between systems, and exit codes are only meaningful on the same os and architecture.
line	is the line number where the task was found in the main sequence file. Setup- and cleanup tasks don't have this attribute.
pid	is the process id under which the application had run.
app	is the path to the application that was started. As with the progress record, any pegasus-kickstart will be parsed out so that you see the true application.

pegasus-cluster Summary

The final summary of counts is a record bracketed by square brackets like this (broken over two lines for readability):

```
[cluster-summary stat="ok", lines=3, tasks=3, succeeded=3, failed=0, extra=0,
duration=1.143, start="2011-04-27T14:31:25.338-07:00", pid=18542, app="./seqexec"]
```

The record is introduced by the string *cluster-summary* with the following constituents:

stat	The string <i>fail</i> when pegasus-cluster would return with an exit status of 5. Concretely, this is any failure in <i>default</i> mode, and first failure in -f mode. Otherwise, it will always be the string <i>ok</i> , if the record is produced.
lines	is the stopping line number of the input sequence file, indicating how far processing got. Up to the number of cores additional lines may have been parsed in case of -f mode.
tasks	is the number of tasks processed.
succeeded	is the number of main sequence jobs that succeeded.
failed	is the number of main sequence jobs that failed. The failure condition depends on the -S settings, too.
extra	is 0, 1 or 2, depending on the existence of setup- and cleanup jobs.
duration	is the duration in seconds, with millisecond resolution, how long *pegasus-cluster ran.
start	is the start time of pegasus-cluster as ISO 8601 time stamp.

See Also

pegasus-kickstart(1)

Caveats

The **-S** option sets success codes globally. It is not possible to activate success codes only for one specific application, and doing so would break the shell compatibility. Due to the global nature, use success codes sparingly as last resort emergency handler. In better plannable environments, you should use an application wrapper instead.

Example

The following shows an example input file to **pegasus-cluster** making use of **pegasus-kickstart** to track applications.

```
#
# mkdir
/path/to/pegasus-kickstart -R HPC -n mkdir /bin/mkdir -m 2755 -p split-corpus split-ne-corpus
#
# drop-dian
/path/to/pegasus-kickstart -H -R HPC -n drop-dian -o '^f-new.plain' /path/to/drop-dian /path/to/f-
tok.plain /path/to/f-tok.NE
#
# split-corpus
/path/to/pegasus-kickstart -H -R HPC -n split-corpus /path/to/split-seq-new.pl 23 f-new.plain split-
corpus/corpus.
#
# split-corpus
/path/to/pegasus-kickstart -H -R HPC -n split-corpus /path/to/split-seq-new.pl 23 /path/to/f-tok.NE
split-ne-corpus/corpus.
```

Environment Variables

A number of environment variables permits to influence the behavior of **pegasus-cluster** during run-time.

SEQEXEC_PROGRESS_REPORTIf this variable is set, and points to a writable file location, progress report records are appended to the file. While care is taken to atomically append

records to the log file, in case concurrent instances of **pegasus-cluster** are running, broken Linux NFS may still garble some content.

SEQEXEC_CPUS

If this variable is set to a non-negative integer, that many CPUs are attempted to be used. The special value *auto* permits to auto-detect the number of CPUs available to **pegasus-cluster** on the system.

SEQEXEC_SETUP

If this variable is set, and contains a single fully-qualified path to an executable and arguments, this executable will be run before any jobs are started. The exit code of this setup job will have no effect upon the main job sequence. Success or failure will not be counted towards the summary.

SEQEXEC_CLEANUP

If this variable is set, and contains a single fully-qualified path to an executable and arguments, this executable will be before **pegasus-cluster** quits. Failure of any previous job will have no effect on the ability to run this job. The exit code of the cleanup job will have no effect on the overall success or failure state. Success or failure will not be counted towards the summary.

History

As you may have noticed, **pegasus-cluster** had the name **seqexec** in previous incantations. We are slowly moving to the new name to avoid clashes in a larger OS installation setting. However, there is no pertinent need to change the internal name, too, as no name clashes are expected.

Authors

Jens-S. Vöckler <voeckler at isi dot edu>

Pegasus <http://pegasus.isi.edu/>

Name

pegasus-config — The authority for where parts of the Pegasus system exists on the filesystem. **pegasus-config** can be used to find libraries such as the DAX generators.

Synopsis

```
pegasus-config [-h] [--help] [-V] [--version] [--noeoln]
                [--perl-dump] [--perl-hash] [--python-dump] [--sh-dump]
                [--bin] [--conf] [--java] [--perl] [--python]
                [--python-externals] [--schema] [--classpath]
                [--local-site] [--full-local]
```

Description

pegasus-config is used to find locations of Pegasus system components. The tool is used internally in Pegasus and by users who need to find paths for DAX generator libraries and schemas.

Options

-h , --help	Prints help and exits.
-V , --version	Prints Pegasus version information
--perl-dump	Dumps all settings in perl format as separate variables.
--perl-hash	Dumps all settings in perl format as single perl hash.
--python-dump	Dumps all settings in python format.
--sh-dump	Dumps all settings in shell format.
--bin	Print the directory containing Pegasus binaries.
--conf	Print the directory containing configuration files.
--java	Print the directory containing the jars.
--perl	Print the directory to include into your PERL5LIB.
--python	Print the directory to include into your PYTHONLIB.
--python-externals	Print the directory to the external Python libraries.
--schema	Print the directory containing schemas.
--classpath	Builds a classpath containing the Pegasus jars.
--noeoln	Do not produce a end-of-line after output. This is useful when being called from non-shell backticks in scripts. However, order is important for this option: If you intend to use it, specify it first.
--local-site [d]	Create a site catalog entry for site "local". This is only an XML snippet without root element nor XML headers. The optional argument "d" points to the mount point to use. If not specified, defaults to the user's \$HOME directory.
--full-local [d]	Create a complete site catalog with only site "local". The an XML snippet without root element nor XML headers. The optional argument "d" points to the mount point to use. If not specified, defaults to the user's \$HOME directory.

Example

To set the PYTHONPATH variable in your shell for using the Python DAX API:

```
export PYTHONPATH=`pegasus-config --python`
```

To set the same path inside Python:

```
config = subprocess.Popen("pegasus-config --python-dump", stdout=subprocess.PIPE,  
    shell=True).communicate()[0]  
exec config
```

To set the PERL5LIB variable in your shell for using the Perl DAX API:

```
export PERL5LIB=`pegasus-config --perl`
```

To set the same path inside Perl:

```
eval `pegasus-config --perl-dump`;  
die("Unable to eval pegasus-config output: $@" if $@;
```

will set variables a number of lexically local-scoped **my** variables with prefix "pegasus_" and expand Perl's search path for this script.

Alternatively, you can fail early and collect all Pegasus-related variables into a single global %pegasus variable for convenience:

```
BEGIN {  
    eval `pegasus-config --perl-hash`;  
    die("Unable to eval pegasus-config output: $@" if $@;  
}
```

Author

Pegasus Team <http://pegasus.isi.edu>

Name

`pegasus-create-dir` — Creates work directories in Pegasus workflows.

Synopsis

pegasus-create-dir [-h][-l *level*][-u *URL*]

Description

pegasus-create-dir creates a directory for the given URL. Some of the protocols it can handle are GridFTP, SRM, Amazon S3, HTTP, and file:// (using `mkdir`).

Options

-h , --help	Prints a usage summary with all the available command-line options.
-l <i>level</i> , --loglevel <i>level</i>	The debugging output level. Valid values are <i>debug</i> , <i>info</i> , <i>warning</i> , and <i>error</i> . Default value is <i>info</i> .
-u <i>URL</i> , --url <i>URL</i>	Specifies the directory to create.

Example

```
$ pegasus-create-dir -u gsiftp://somehost/some/path
```

Authors

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-dagman — Wrapper around `*condor_dagman*`. Not to be run by user.

Description

The **pegasus-dagman** is a python wrapper that invokes **pegasus-monitord** and **condor_dagman** both. This is started automatically by **pegasus-submit-dag** and ultimately **condor_submit_dag**. **DO NOT USE DIRECTLY**

Return Value

If the **condor_dagman** and **pegasus-monitord** exit successfully, **pegasus-dagman** exits with 0, else exits with non-zero.

Environment Variables

PATH The path variable is used to locate binary for **condor_dagman** and **pegasus-monitord**

Pegasus Team <http://pegasus.isi.edu>

Name

`pegasus-dax-validator` — determines if a given DAX file is valid.

Synopsis

`pegasus-dax-validator` *daxfile* [*verbose*]

Description

The **pegasus-dax-validator** is a simple application that determines, if a given DAX file is valid XML. For this, it parses the file with as many XML validity checks that the Apache Xerces XML parser framework supports.

Options

<i>daxfile</i>	The location of the file containing the DAX.
<i>verbose</i>	If any kind of second argument was specified, not limited to the string <i>verbose</i> , the verbose output mode is switched on.

Return Value

If the DAX was parsed successfully, or only *warning's were issued*, the exit code is 0. Any *'error* or *'fatal error* will result in an exit code of 1.

Additionally, a summary statistics with counts of warnings, errors, and fatal errors will be displayed.

Example

The following shows the parsing of a DAX file that uses the wrong kind of value for certain enumerations. The output shows the errors with the respective line number and column number of the input DAX file, so that one can find and fix them more easily. (The lines in the example were broken to fit the manpage format.)

```
$ pegasus-dax-validator bd.dax
ERROR in line 14, col 110: cvc-enumeration-valid: Value 'i386' is not
facet-valid with respect to enumeration '[x86, x86_64, ppc, ppc_64,
ia64, sparcv7, sparcv9, amd64]'. It must be a value from the
enumeration.
ERROR in line 14, col 110: cvc-attribute.3: The value 'i386' of
attribute 'arch' on element 'executable' is not valid with respect to
its type, 'ArchitectureType'.
ERROR in line 14, col 110: cvc-enumeration-valid: Value 'darwin' is
not facet-valid with respect to enumeration '[aix, sunos, linux, macosx,
windows]'. It must be a value from the enumeration.
ERROR in line 14, col 110: cvc-attribute.3: The value 'darwin' of
attribute 'os' on element 'executable' is not valid with respect to
its type, 'OSType'.

0 warnings, 4 errors, and 0 fatal errors detected.
```

Name

pegasus-exitcode — Checks the stdout/stderr files of a workflow job for any indication that an error occurred in the job. This script is intended to be invoked automatically by DAGMan as the POST script of a job.

Synopsis

pegasus-exitcode [-h][-t *n*][-r *rv*][-n] *job.out*

Description

pegasus-exitcode is a utility that examines the STDOUT of a job to determine if the job failed, and renames the STDOUT and STDERR files of a job to preserve them in case the job is retried.

Pegasus uses **pegasus-exitcode** as the DAGMan postscript for all jobs submitted via Globus GRAM. This tool exists as a workaround to a known problem with Globus where the exitcodes of GRAM jobs are not returned. This is a problem because Pegasus uses the exitcode of a job to determine if the job failed or not.

In order to get around the exitcode problem, Pegasus wraps all GRAM jobs with Kickstart, which records the exitcode of the job in an XML invocation record, which it writes to the job's STDOUT. The STDOUT is transferred from the execution host back to the submit host when the job terminates. After the job terminates, DAGMan runs the job's postscript, which Pegasus sets to be **pegasus-exitcode**. **pegasus-exitcode** looks at the invocation record generated by kickstart to see if the job succeeded or failed. If the invocation record indicates a failure, then **pegasus-exitcode** returns a non-zero result, which indicates to DAGMan that the job has failed. If the invocation record indicates that the job succeeded, then **pegasus-exitcode** returns 0, which tells DAGMan that the job succeeded.

pegasus-exitcode performs several checks to determine whether a job failed or not. These checks include:

1. Is STDOUT empty? If it is empty, then the job failed.
2. Are there any <status> tags with a non-zero value? If there are, then the job failed. Note that, if this is a clustered job, there could be multiple <status> tags, one for each task. If any of them are non-zero, then the job failed.
3. Is there at least one <status> tag with a zero value? There must be at least one successful invocation or the job has failed.

In addition, **pegasus-exitcode** allows the caller to specify the exitcode returned by Condor using the **--return** argument. This can be passed to **pegasus-exitcode** in a DAGMan post script by using the \$RETURN variable. If this value is non-zero, then **pegasus-exitcode** returns a non-zero result before performing any other checks. For GRAM jobs, the value of \$RETURN will always be 0 regardless of whether the job failed or not.

Also, **pegasus-exitcode** allows the caller to specify the number of successful tasks it should see using the **--tasks** argument. If **pegasus-exitcode** does not see N successful tasks, where N is set by **--tasks**, then it will return a non-zero result. The default value is 1. This can be used to detect failures in clustered jobs where, for any number of reasons, invocation records do not get generated for all the tasks in the clustered job.

In addition to checking the success/failure of a job, **pegasus-exitcode** also renames the STDOUT and STDERR files of the job so that if the job is retried, the STDOUT and STDERR of the previous run are not lost. It does this by appending a sequence number to the end of the files. For example, if the STDOUT file is called "job.out", then the first time the job is run **pegasus-exitcode** will rename the file "job.out.000". If the job is run again, then **pegasus-exitcode** sees that "job.out.000" already exists and renames the file "job.out.001". It will continue to rename the file by incrementing the sequence number every time the job is executed.

Options

- | | |
|--|--|
| -h , --help | Prints a usage summary with all the available command-line options. |
| -t <i>n</i> , --tasks <i>n</i> | Number of tasks expected. If less than <i>n</i> tasks succeeded, then pegasus-exitcode will fail with a non-zero return value. This is used in cases where we may not get a Kickstart invocation record for some tasks. Normally Seqexec will detect failed Kickstart invocations and fail accordingly. |

- r *rv* , --return *rv*** Return value reported by DAGMan. This can be specified in the DAG using the \$RETURN variable. If this is non-zero, then **pegasus-exitcode** immediately fails with a non-zero return value itself. If it is zero, then just rotate the file and don't check for proper kickstart output. This option can be used in cases where kickstart cannot be used (such as pegasus-create-dir) to enable file rotation.
- n , --no-rename** Don't rename *job.out* and *job.err* to *.out.XXX* and *.err.XXX*. This option is used primarily for testing.

Name

`pegasus-gridftp` — Perform file and directory operations on remote GridFTP servers

Synopsis

```
pegasus-gridftp ls [options] [URL...]  
pegasus-gridftp mkdir [options] [URL...]  
pegasus-gridftp rm [options] [URL...]
```

Description

pegasus-gridftp is a client for Globus GridFTP servers. It enables remote operations on files and directories via the GridFTP protocol. This tool was created to enable more efficient remote directory creation and file cleanup tasks in Pegasus.

Options

Global Options

- v** Turn on verbose output. Verbosity can be increased by specifying multiple **-v** arguments.
- i FILE** Read a list of URLs to operate on from FILE.

rm Options

- f** If the URL does not exist, then ignore the error.
- r** Recursively delete files and directories.

ls Options

- a** List files beginning with a ".".
- l** Create a long-format listing with file size, creation date, type, permissions, etc.

mkdir Options

- p** Create intermediate directories as necessary.
- f** Ignore error if directory already exists

Subcommands

pegasus-gridftp has several subcommands to implement different operations.

- ls** The **ls** subcommand lists the details of a file, or the contents of a directory on the remote server.
- mkdir** The **mkdir** subcommand creates one or more directories on the remote server.
- rm** The **rm** subcommand deletes one or more files and directories from the remote server.

URL Format

All URLs supplied to **pegasus-gridftp** should begin with "gsiftp://".

Configuration

pegasus-gridftp uses the CoG JGlobus API to communicate with remote GridFTP servers. Refer to the CoG JGlobus documentation for information about configuring the API, such as how to specify the user's proxy, etc.

Return Value

pegasus-gridftp returns a zero exist status if the operation is successful. A non-zero exit status is returned in case of failure.

Name

`pegasus-invoke` — invokes a command from a file

Synopsis

`pegasus-invoke (app | @fn) [arg | *@fn [..]]`

Description

The **pegasus-invoke** tool invokes a single application with as many arguments as your Unix permits (128k characters for Linux). Arguments are come from two places, either the command-line as regular arguments, or from a special file, which contains one argument per line.

The **pegasus-invoke** tool became necessary to work around the 4k argument length limit in Condor. It also permits to use arguments inside argument files without worry about shell, Condor or Globus escape necessities. All argument file contents are passed as is, one line per argument entry.

Arguments

- d** This option increases the debug level. Currently, only debugging or no debugging is distinguished. Debug message are generated on *stdout* . By default, debugging is disabled.
- h** This option prints the help message and exits the program.
- This option stops any option processing. It may only be necessary, if the application is stated on the command-line, and starts with a hyphen itself. The first argument must either be the application to run as fully-specified location (either absolute, or relative to current wd), or a file containing one argument per line. The *PATH* environment variables is **not** used to locate an application. Subsequent arguments may either be specified explicitly on the commandline. Any argument that starts with an at (@) sign is taken to introduce a filename, which contains one argument per line. The textual file may contain long arguments and filenames. However, Unices still impose limits on the maximum length of a directory name, and the maximum length of a file name. These lengths are not checked, because **pegasus-invoke** is oblivious of the application (e.g. what argument is a filename, and what argument is a mere string resembling a filename).

Return Value

The **pegasus-invoke** tool returns 127, if it was unable to find the application. It returns 126, if there was a problem parsing the file. All other exit status, including 126 and 127, come from the application.

See Also

pegasus-kickstart(1)

Example

```
$ echo "/bin/date" > X
$ echo "-Isec" >> X
$ pegasus-invoke @X
2005-11-03T15:07:01-0600
```

Recursion is also possible. Please mind not to use circular inclusions. Also note how duplicating the initial at (@) sign will escape its meaning as inclusion symbol.

```
$ cat test.3
This is test 3

$ cat test.2
/bin/echo
@test.3
@@test.3

$ pegasus-invoke @test.2
This is test 3 @test.3
```

Restrictions

While the arguments themselves may contain files with arguments to parse, starting with an at (@) sign as before, the maximum recursion limit is 32 levels of inclusions. It is not possible (yet) to use *stdin* as source of inclusion.

History

As you may have noticed, **pegasus-invoke** had the name **invoke** in previous incantations. We are slowly moving to the new name to avoid clashes in a larger OS installation setting. However, there is no pertinent need to change the internal name, too, as no name clashes are expected.

Pegasus <http://pegasus.isi.edu/>

Name

pegasus-keg — kanonical executable for grids

Synopsis

```
pegasus-keg [-a appname] [-t interval [-T interval]] [-l logname]
              [-P prefix] [-o fn [..]] [-i fn [..]] [-G sz]
              [-C] [-e env [..]] [-p parm [..]]
```

Description

The kanonical executable is a stand-in for regular binaries in a DAG - but not for their arguments. It allows to trace the shape of the execution of a DAG, and thus is an aid to debugging DAG related issues.

Key feature of **pegasus-keg** is that it can copy any number of input files, including the *generator* case, to any number of output files, including the *datasink* case. In addition, it protocols the IPv4 and hostname of the host it ran upon, the current timestamp, and the run time from start til the point of logging the information, the current working directory and some information on the system environment. **pegasus-keg** will also report all input files, the current output files and any requested string and environment value.

Arguments

The **-e**, **-i**, **-o** and **-p** arguments allow lists with arbitrary number of arguments. These options may also occur repeatedly on the command line. The file options may be provided with the special filename **-** to indicate *stdout* in append mode for writing, or *stdin* for reading. The **-a**, **-l**, **-P**, **-T** and **-t** arguments should only occur a single time with a single argument.

If **pegasus-keg** is called without any arguments, it will display its usage and exit with success.

-a appname	This option allows pegasus-keg to display a different name as its applications. This mode of operation is useful in make-believe mode. The default is the basename of <i>argv[0]</i> .
-e env [..]	This option names any number of environment variables, whose value should be reported as part of the data dump. By default, no environment variables are reported.
-i infile [..]	The pegasus-keg binary can work on any number of input files. For each output file, every input file will be opened, and its content copied to the output file. Textual input files are assumed. Each input line is indented by two spaces. The input file content is bracketed between an start and end section, see below. By default, pegasus-keg operates in <i>generator</i> mode.
-l logfile	The <i>logfile</i> is the name of a file to append atomically the self-info, see below. The atomic write guarantees that the multi-line information will not interleave with other processes that simultaneously write to the same file. The default is not to use any log file.
-o outfile [..]	The pegasus-keg can work on any number of output files. For each output file, every input file will be opened, and its content copied to the output file. Textual input files are assumed. Each input line is indented by two spaces. The input file content is bracketed between an start and end section, see 2nd example. After all input files are copied, the data dump from this instance of pegasus-keg is appended to the output file. Without output files, pegasus-keg operates in <i>data sink</i> mode.
-G size	If you want pegasus-keg to generate a lot of output, the generator option will do that for you. Just specify how much, in bytes, you want. This option is off by default.
-C	This option causes pegasus-keg to list all environment variables that start with the prefix <i>_CONDOR</i> . The option is useful, if <i>.B</i> pegasus-keg is run as (part of) a Condor job. This option is off by default.
-p string [..]	Any number of parameters can be reported, without being specific on their content. Effectively, these strings are copied straight from the command line. By default, no extra arguments are shown.

-P prefix	Each line from every input file is indented with a prefix string to visually emphasize the provenance of an input files through multiple instances of pegasus-keg . By default, two spaces are used as prefix string.
-t interval	The interval is an amount of sleep time that the pegasus-keg executable is to sleep. This can be used to emulate light work without straining the pool resources. If used together with the -T spin option, the sleep interval comes before the spin interval. The default is no sleep time.
-T interval	The interval is an amount of busy spin time that the pegasus-keg executable is to simulate intense computation. The simulation is done by random julia set calculations. This option can be used to emulate an intense work to strain pool resources. If used together with the -t sleep option, the sleep interval comes before the spin interval. The default is no spin time.

Return Value

Execution as planned will return 0. The failure to open an input file will return 1, the failure to open an output file, including the log file, will return with exit code 2.

Example

The example shows the bracketing of an input file, and the copy produced on the output file. For illustration purposes, the output file is connected to *stdout* :

```
$ date > xx
$ pegasus-keg -i xx -p a b c -o -
--- start xx ----
  Thu May  5 10:55:45 PDT 2011
--- final xx ----
Timestamp Today: 20110505T105552.910-07:00 (1304618152.910;0.000)
Applicationname: pegasus-keg [3661M] @ 128.9.xxx.xxx (xxx.isi.edu)
Current Workdir: /opt/pegasus/default/bin/pegasus-keg
Systemenvironm.: x86_64-Linux 2.6.18-238.9.1.el5
Processor Info.: 4 x Intel(R) Core(TM) i5 CPU          750 @ 2.67GHz @ 2660.068
Load Averages  : 0.298 0.135 0.104
Memory Usage MB: 11970 total, 8089 free, 0 shared, 695 buffered
Swap Usage MB: 12299 total, 12299 free
Filesystem Info: /                ext3      62GB total,    20GB avail
Filesystem Info: /lfs/balefire    ext4     1694GB total,  1485GB avail
Filesystem Info: /boot            ext2     493MB total,   447MB avail
Output Filename: -
Input Filenames: xx
Other Arguments: a b c
```

Restrictions

The input file must be textual files. The behaviour with binary files is unspecified.

The host address is determined from the primary interface. If there is no active interface besides loopback, the host address will default to 0.0.0.0. If the host address is within a *virtual private network* address range, only (VPN) will be displayed as hostname, and no reverse address lookup will be attempted.

The *processor info* line is only available on Linux systems. The line will be missing on other operating systems. Its information is assuming symmetrical multi processing, reflecting the CPU name and speed of the last CPU available in */dev/cpuinfo* .

There is a limit of *4 * page size* to the output buffer of things that .B pegasus-keg can report in its self-info dump. There is no such restriction on the input to output file copy.

Pegasus - <http://pegasus.isi.edu/>

Name

pegasus-kickstart — run an executable in a more universal environment.

Synopsis

```
pegasus-kickstart [-n tr] [-N dv] [-H] [-R site] [-W | -w dir]
                  [-L lbl -T iso] [-s p | @fn] [-S p | @fn] [-i fn]
                  [-o fn] [-e fn] [-X] [-I fn sz] [-F] (-I fn | app [appflags])
pegasus-kickstart -V
```

Description

The **pegasus-kickstart** executable is a light wrapper program which connects the *stdin*, *stdout* and *stderr* file handles for grid jobs on the remote site, and reports back the remote application termination condition.

Sitting in between the remote scheduler and the executable, it is possible for **pegasus-kickstart** to gather additional information about the executable run-time behavior and resource usage, including the exit status of jobs. This information is important for the Pegasus invocation tracking as well as to Condor DAGMan's awareness of Globus job failures.

pegasus-kickstart allows the optional execution of jobs before and after the main application job that run in chained execution with the main application job. See section **SUBJOBS** for details about this feature.

All jobs with relative path specifications to the application are part of search relative to the current working directory (yes, this is unsafe), and by prepending each component from the *PATH* environment variable. The first match is used. Jobs that use absolute pathnames, starting in a slash, are exempt. Using an absolute path to your executable is the safe and recommended option.

pegasus-kickstart rewrites the command line of any job (pre, post and main) with variable substitutions from Unix environment variables. See section **VARIABLE REWRITING** below for details on this feature.

Options

- | | |
|--------------------------------------|---|
| -n <i>tr</i> | In order to associate the minimal performance information of the job with the invocation records, the jobs needs to carry which <i>transformation</i> was responsible for producing it. The format is the textual notation for fully-qualified definition names, like namespace::name:version, with only the name portion being mandatory.

There is no default. If no value is given, "null" will be reported. |
| -N <i>dv</i> | The jobs may carry which instantiation of a transformation was responsible for producing it. The format is the textual notation for fully-qualified definition names, like namespace::name:version, with only the name portion being mandatory.

There is no default. If no value is given, "null" will be reported. |
| -H | This option avoids pegasus-kickstart writing the XML preamble (entity), if you need to combine multiple pegasus-kickstart records into one document.

Additionally, if specified, the environment and the resource usage segments will not be written, assuming that a in a concatenated record version, the initial run will have captured those settings. |
| -R <i>site</i> | In order to provide the greater picture, pegasus-kickstart can reflect the site handle (resource identifier) into its output.

There is no default. If no value is given, the attribute will not be generated. |
| -L <i>lbl</i> , -T <i>iso</i> | These optional arguments denote the workflow label (from DAX) and the workflow's last modification time (from DAX). The label <i>lbl</i> can be any sensible string of up to 32 characters, but should use C identifier characters. The timestamp <i>iso</i> must be an ISO 8601 compliant time-stamp. |

- S l=p** If stat information on any file is required *before* any jobs were started, logical to physical file mappings to stat can be passed using the **-S** option. The LFN and PFN are concatenated by an equals (=) sign. The LFN is optional: If no equals sign is found, the argument is taken as sole PFN specification without LFN.
- This option may be specified multiple times. To reduce and overcome command line length limits, if the argument is prefixed with an at (@) sign, the argument is taken to be a textual file of LFN to PFN mappings. The optionality mentioned above applies. Each line inside the file argument is the name of a file to stat. Comments (#) and empty lines are permitted.
- Each PFN will incur a *statcall* record (element) with attribute *id* set to value *initial*. The optional *lfn* attribute is set to the LFN stat'ed. The filename is part of the *statinfo* record inside.
- There is no default.
- s fn** If stat information on any file is required *after* all jobs have finished, logical to physical file mappings to stat can be passed using the **-s** option. The LFN and PFN are concatenated by an equals (=) sign. The LFN is optional: If no equals sign is found, the argument is taken as sole PFN specification without LFN.
- This option may be specified multiple times. To reduce and overcome commandline length limits, if the argument is prefixed with an at (@) sign, the argument is taken to be a textual file of LFN to PFN mappings. The optionality mentioned above applies. Each line inside the file argument is the name of a file to stat. Comments (#) and empty lines are permitted.
- Each PFN will incur a *statcall* record (element) with attribute *id* set to value *final*. The optional *lfn* attribute is set to the LFN stat'ed. The filename is part of the *statinfo* record inside.
- There is no default.
- i fn** This option allows **pegasus-kickstart** to re-connect the *stdin* of the application that it starts. Use a single hyphen to share *stdin* with the one provided to **pegasus-kickstart**.
- The default is to connect *stdin* to */dev/null*.
- o fn** This option allows **pegasus-kickstart** to re-connect the *stdout* of the application that it starts. The mode is used whenever an application produces meaningful results on its *stdout* that need to be tracked by Pegasus. The real *stdout* of Globus jobs is staged via GASS (GT2) or RFT (GT4). The real *stdout* is used to propagate the invocation record back to the submit site. Use the single hyphen to share the application's *stdout* with the one that is provided to **pegasus-kickstart**. In that case, the output from **pegasus-kickstart** will interleave with application output. For this reason, such a mode is not recommended.
- In order to provide an un-captured *stdout* as part of the results, it is the default to connect the *stdout* of the application to a temporary file. The content of this temporary file will be transferred as payload data in the **pegasus-kickstart** results. The content size is subject to payload limits, see the **-B** option. If the content grows large, only an initial portion will become part of the payload. If the temporary file grows too large, it may flood the worker node's temporary space. The temporary file will be deleted after **pegasus-kickstart** finishes.
- If the filename is prefixed with an exclamation point, the file will be opened in append mode instead of overwrite mode. Note that you may need to escape the exclamation point from the shell.
- The default is to connect *stdout* to a temporary file.
- e fn** This option allows **pegasus-kickstart** to re-connect the *stderr* of the application that it starts. This option is used whenever an application produces meaningful results on *stderr* that needs tracking by Pegasus. The real *stderr* of Globus jobs is staged via GASS (GT2) or RFT (GT4). It is used to propagate abnormal behavior from both, **pegasus-kickstart** and the application that it starts, though its main use is to propagate application dependent data and heartbeats. Use a single hyphen to share *stderr* with the *stderr* that is provided to **pegasus-kickstart**. This is the backward compatible behavior.

In order to provide an un-captured *stderr* as part of the results, by default the *stderr* of the application will be connected to a temporary file. Its content is transferred as payload data in the **pegasus-kickstart** results. If too large, only the an initial portion will become part of the payload. If the temporary file grows too large, it may flood the worker node's temporary space. The temporary file will be deleted after **pegasus-kickstart** finishes.

If the filename is prefixed with an exclamation point, the file will be opened in append mode instead of overwrite mode. Note that you may need to escape the exclamation point from the shell.

The default is to connect *stderr* to a temporary file.

-l logfn allows to append the performance data to the specified file. Thus, multiple XML documents may end up in the same file, including their XML preamble. *stdout* is normally used to stream back the results. Usually, this is a GASS-staged stream. Use a single hyphen to generate the output on the *stdout* that was provided to **pegasus-kickstart**, the default behavior.

Default is to append the invocation record onto the provided *stdout*.

-w dir permits the explicit setting of a new working directory once pegasus-kickstart is started. This is useful in a remote scheduling environment, when the chosen working directory is not visible on the job submitting host. If the directory does not exist, **pegasus-kickstart** will fail. This option is mutually exclusive with the **-W dir** option.

Default is to use the working directory that the application was started in. This is usually set up by a remote scheduling environment.

-W dir permits the explicit creation and setting of a new working directory once pegasus-kickstart is started. This is useful in a remote scheduling environment, when the chosen working directory is not visible on the job submitting host. If the directory does not exist, **pegasus-kickstart** will attempt to create it, and then change into it. Both, creation and directory change may still fail. This option is mutually exclusive with the **-w dir** option.

Default is to use the working directory that the application was started in. This is usually set up by a remote scheduling environment.

-X make an application executable, no matter what. It is a work-around code for a weakness of **globus-url-copy** which does not copy the permissions of the source to the destination. Thus, if an executable is staged-in using GridFTP, it will have the wrong permissions. Specifying the **-X** flag will attempt to change the mode to include the necessary x (and r) bits to make the application executable.

Default is not to change the mode of the application. Note that this feature can be misused by hackers, as it is attempted to call *chmod* on whatever path is specified.

-B sz varies the size of the debug output data section. If the file descriptors *stdout* and *stderr* remain untracked, **pegasus-kickstart** tracks that output in temporary files. The first few pages from this output is copied into a data section in the output. In order to resize the length of the output within reasonable boundaries, this option permits a changes. Data beyond the size will not be copied, i.e. is truncated.

Warning: This is not a cheap way to obtain the stdio file handle data. Please use tracked files for that. Due to output buffer pre-allocation, using arbitrary large arguments may result in failures of **pegasus-kickstart** itself to allocate the necessary memory.

The default maximum size of the data section is 262144 byte.

-F This flag will issue an explicit *fsync()* call on kickstart's own *stdout* file. Typically you won't need this flag. Albeit, certain shared file system situations may improve when adding a flush after the written invocation record.

The default is to just use kickstart's NFS alleviation strategy by locking and unlocking *stdout*.

-I fn In this mode, the application name and any arguments to the application are specified inside of file *fn*. The file contains one argument per line. Escaping from Globus, Condor and shell meta characters is

not required. This mode permits to use the maximum possible command line length of the underlying operating system, e.g. 128k for Linux. Using the **-I** mode stops any further command line processing of **pegasus-kickstart** command lines.

Default is to use the *app flags* mode, where the application is specified explicitly on the command-line.

-f	This flag causes kickstart to output full information, including the environment and resource limits under which the job ran, and any useful auxiliary statcalls. If the job fails, then -f is implied.
-t	This flag causes kickstart to skip tracing the child process and omit the <proc> element. This flag only exists when kickstart is compiled for Linux.
-q	This flag causes kickstart to omit the <data> part of the <statcall> records when the job exits successfully. This is designed to reduce the size of the output logs for large workflows.
<i>app</i>	The path to the application has to be completely specified. The application is a mandatory option.
<i>appflags</i>	Application may or may not have additional flags.

Return Value

pegasus-kickstart will return the return value of the main job. In addition, the error code 127 signals that the call to exec failed, and 126 that reconnecting the stdio failed. A job failing with the same exit codes is indistinguishable from **pegasus-kickstart** failures.

pegasus-plan(1), condor_submit_dag(1), condor_submit(1), getrusage(3c).

<http://pegasus.isi.edu/wms/docs/schemas/iv-2.2/iv-2.2.html>

<http://pegasus.isi.edu/documentation>

Subjobs

Subjobs are a new feature and may have a few wrinkles left.

In order to allow specific setups and assertion checks for compute nodes, **pegasus-kickstart** allows the optional execution of a *prejob*. This *prejob* is anything that the remote compute node is capable of executing. For modern Unix systems, this includes `#!` scripts interpreter invocations, as long as the x bits on the executed file are set. The main job is run if and only if the *prejob* returned regularly with an exit code of zero.

With similar restrictions, the optional execution of a *postjob* is chained to the success of the main job. The *postjob* will be run, if the main job terminated normally with an exit code of zero.

In addition, a user may specify a *setup* and a *cleanup* job. The *setup* job sets up the remote execution environment. The *cleanup* job may tear down and clean-up after any job ran. Failure to run the setup job has no impact on subsequent jobs. The cleanup is a job that will even be attempted to run for all failed jobs. No job information is passed. If you need to invoke multiple setup or clean-up jobs, bundle them into a script, and invoke the clean-up script. Failure of the clean-up job is not meant to affect the progress of the remote workflow (DAGMan). This may change in the future.

The setup-, pre-, and post- and cleanup-job run on the same compute node as the main job to execute. However, since they run in separate processes as children of **pegasus-kickstart**, they are unable to influence each others nor the main jobs environment settings.

All jobs and their arguments are subject to variable substitutions as explained in the next section.

To specify the *prejob*, insert the the application invocation and any optional commandline argument into the environment variable `GRIDSTART_PREJOB`. If you are invoking from a shell, you might want to use single quotes to protect against the shell. If you are invoking from Globus, you can append the RSL string feature. From Condor, you can use Condor's notion of environment settings. In Pegasus use the *profile* command to set generic scripts that will work on

multiple sites, or the transformation catalog to set environment variables in a pool-specific fashion. Please remember that the execution of the main job is chained to the success of the prejob.

To set up the postjob, use the environment variable `GRIDSTART_POSTJOB` to point to an application with potential arguments to execute. The same restrictions as for the prejob apply. Please note that the execution of the post job is chained to the main job.

To provide the independent setup job, use the environment variable `GRIDSTART_SETUP`. The exit code of the setup job has no influence on the remaining chain of jobs. To provide an independent cleanup job, use the environment variable `GRIDSTART_CLEANUP` to point to an application with possible arguments to execute. The same restrictions as for prejob and postjob apply. The cleanup is run regardless of the exit status of any other jobs.

Variable Rewriting

Variable substitution is a new feature and may have a few wrinkles left.

The variable substitution employs simple rules from the Bourne shell syntax. Simple quoting rules for backslashed characters, double quotes and single quotes are obeyed. Thus, in order to pass a dollar sign to as argument to your job, it must be escaped with a backslash from the variable rewriting.

For pre- and postjobs, double quotes allow the preservation of whitespace and the insertion of special characters like `\a` (alarm), `\b` (backspace), `\n` (newline), `\r` (carriage return), `\t` (horizontal tab), and `\v` (vertical tab). Octal modes are *not* allowed. Variables are still substituted in double quotes. Single quotes inside double quotes have no special meaning.

Inside single quotes, no variables are expanded. The backslash only escapes a single quote or backslash.

Backticks are not supported.

Variables are only substituted once. You cannot have variables in variables. If you need this feature, please request it.

Outside quotes, arguments from the pre- and postjob are split on linear whitespace. The backslash makes the next character verbatim.

Variables that are rewritten must start with a dollar sign either outside quotes or inside double quotes. The dollar may be followed by a valid identifier. A valid identifier starts with a letter or the underscore. A valid identifier may contain further letters, digits or underscores. The identifier is case sensitive.

The alternative use is to enclose the identifier inside curly braces. In this case, almost any character is allowed for the identifier, including whitespace. This is the *only* curly brace expansion. No other Bourne magic involving curly braces is supported.

One of the advantages of variable substitution is, for example, the ability to specify the application as `$HOME/bin/app1` in the transformation catalog, and thus to gridstart. As long as your home directory on any compute node has a `bin` directory that contains the application, the transformation catalog does not need to care about the true location of the application path on each pool. Even better, an administrator may decide to move your home directory to a different place. As long as the compute node is set up correctly, you don't have to adjust any Pegasus data.

Mind that variable substitution is an expert feature, as some degree of tricky quoting is required to protect substitutable variables and quotes from Globus, Condor and Pegasus in that order. Note that Condor uses the dollar sign for its own variables.

The variable substitution assumptions for the main job differ slightly from the prejob and postjob for technical reasons. The pre- and postjob command lines are passed as one string. However, the main jobs command line is already split into pieces by the time it reaches **pegasus-kickstart**. Thus, any whitespace on the main job's command line must be preserved, and further argument splitting avoided.

It is highly recommended to experiment on the Unix command line with the `echo` and `env` applications to obtain a feeling for the different quoting mechanisms needed to achieve variable substitution.

Example

You can run the **pegasus-kickstart** executable locally to verify that it is functioning well. In the initial phase, the format of the performance data may be slightly adjusted.

```
$ env GRIDSTART_PREJOB='/bin/usleep 250000' \\  
  GRIDSTART_POSTJOB='/bin/date -u' \\  
  pegasus-kickstart -l xx \\$PEGASUS_HOME/bin/keg -T1 -o-  
$ cat xx  
<?xml version="1.0" encoding="ISO-8859-1"?>  
  ...  
  </statcall>  
</invocation>
```

Please take note a few things in the above example:

The output from the postjob is appended to the output of the main job on *stdout*. The output could potentially be separated into different data sections through different temporary files. If you truly need the separation, request that feature.

The log file is reported with a size of zero, because the log file did indeed barely exist at the time the data structure was (re-) initialized. With regular GASS output, it will report the status of the socket file descriptor, though.

The file descriptors reported for the temporary files are from the perspective of **pegasus-kickstart**. Since the temporary files have the close-on-exec flag set, **pegasus-kickstart**s file descriptors are invisible to the job processes. Still, the *'stdio'* of the job processes are connected to the temporary files.

Even this output already appears large. The output may already be too large to guarantee that the append operation on networked pipes (GASS, NFS) are atomically written.

The current format of the performance data is as follows:

Output Format

Refer to <http://pegasus.isi.edu/wms/docs/schemas/iv-2.2/iv-2.2.html> for an up-to-date description of elements and their attributes. Check with <http://pegasus.isi.edu/documentation> for invocation schemas with a higher version number.

Restrictions

There is no version for the Condor *standard* universe. It is simply not possible within the constraints of Condor.

Due to its very nature, **pegasus-kickstart** will also prove difficult to port outside the Unix environment.

Any of the pre-, main-, cleanup and postjob are unable to influence one another's visible environment.

Do not use a Pegasus transformation with just the name *null* and no namespace nor version.

First Condor, and then Unix, place a limit on the length of the command line. The additional space required for the gridstart invocation may silently overflow the maximum space, and cause applications to fail. If you suspect to work with many argument, try an argument-file based approach.

A job failing with exit code 126 or 127 is indistinguishable from **pegasus-kickstart** failing with the same exit codes. Sometimes, careful examination of the returned data can help.

If the logfile is collected into a shared file, due to the size of the data, simultaneous appends on a shared filesystem from different machines may still mangle data. Currently, file locking is not even attempted, although all data is written atomically from the perspective of **pegasus-kickstart**.

The upper limit of characters of command line characters is currently not checked by **pegasus-kickstart**. Thus, some variable substitutions could potentially result in a command line that is larger than permissible.

If the output or error file is opened in append mode, but the application decides to truncate its output file, as in the above example by opening */dev/fd/1* inside *keg*, the resulting file will still be truncated. This is correct behavior, but sometimes not obvious.

Files

**/usr/share/pegasus/schema/
iv-2.2.xsd**

is the suggested location of the latest XML schema describing the data on the submit host.

Environment Variables

GRIDSTART_TMP	is the highest priority to look for a temporary directory, if specified. This rather special variable was introduced to overcome some peculiarities with the FNAL cluster.
TMP	is the next highest priority to look for a temporary directory, if specified.
TEMP	is the next priority for an environment variable denoting a temporary files directory.
TMPDIR	is next in the checklist. If none of these are found, either the <i>stdio</i> definition <i>P_tmpdir</i> is taken, or the fixed string <i>/tmp</i> .
GRIDSTART_SETUP	contains a string that starts a job to be executed unconditionally before any other jobs, see above for a detailed description.
GRIDSTART_PREJOB	contains a string that starts a job to be executed before the main job, see above for a detailed description.
GRIDSTART_POSTJOB	contains a string that starts a job to be executed conditionally after the main job, see above for a detailed description.
GRIDSTART_CLEANUP	contains a string that starts a job to be executed unconditionally after any of the previous jobs, see above for a detailed description.

History

As you may have noticed, **pegasus-kickstart** had the name **kickstart** in previous incarnations. We are slowly moving to the new name to avoid clashes in a larger OS installation setting. However, there is no pertinent need to change the internal name, too, as no name clashes are expected.

Name

pegasus-monitor — tracks a workflow progress, mining information

Synopsis

```
pegasus-monitor [-h|-help] [--verbose|-v]
                [--adjust|-a i] [--foreground|-N]
                [--no-daemon|-n] [--job|-j jobstate.log file]
                [--log|-l logfile] [--conf properties file]
                [--no-recursive] [--no-database] [--no-events]
                [--replay|-r] [--no-notifications]
                [--notifications-max max_notifications]
                [--notifications-timeout timeout]
                [--sim|-s millisleep] [--db-stats]
                [--skip-stdout] [--force|-f]
                [--socket] [--output-dir | -o dir]
                [--dest|-d PATH or URL] [--encoding|-e bp | bson]
                DAGMan output file
```

Description

This program follows a workflow, parsing the output of DAGMAN's dagman.out file. In addition to generating the jobstate.log file, **pegasus-monitor** can also be used mine information from the workflow dag file and jobs' submit and output files, and either populate a database or write a NetLogger events file with that information. **pegasus-monitor** can also perform notifications when tracking a workflow's progress in real-time.

Options

-h , --help	Prints a usage summary with all the available command-line options.
-v , --verbose	Sets the log level for pegasus-monitor . If omitted, the default <i>level</i> will be set to <i>WARNING</i> . When this option is given, the log level is changed to <i>INFO</i> . If this option is repeated, the log level will be changed to <i>DEBUG</i> . The log level in pegasus-monitor can also be adjusted interactively, by sending the <i>USR1</i> and <i>USR2</i> signals to the process, respectively for incrementing and decrementing the log level.
-a <i>i</i> , --adjust <i>i</i>	For adjusting time zone differences by <i>i</i> seconds, default is 0.
-N , --foreground	Do not daemonize pegasus-monitor , go through the motions as if (Condor).
-n , --no-daemon	Do not daemonize pegasus-monitor , keep it in the foreground (for debugging).
-j <i>jobstate.log file</i> , --job <i>jobstate.log file</i>	Alternative location for the <i>jobstate.log</i> file. The default is to write a <i>jobstate.log</i> in the workflow directory. An absolute file name should only be used if the workflow does not have any sub-workflows, as each sub-workflow will generate its own <i>jobstate.log</i> file. If an alternative, non-absolute, filename is given with this option, pegasus-monitor will create one file in each workflow (and sub-workflow) directory with the filename provided by the user with this option. If an absolute filename is provided and sub-workflows are found, a warning message will be printed and pegasus-monitor will not track any sub-workflows.
--log <i>logfile</i> , --log-file <i>logfile</i>	Specifies an alternative <i>logfile</i> to use instead of the <i>monitor.log</i> file in the main workflow directory. Differently from the <i>jobstate.log</i> file above, pegasus-monitor only generates one <i>logfile</i> per execution (and not one per workflow and sub-workflow it tracks).

--conf <i>properties_file</i>	is an alternative file containing properties in the <i>key=value</i> format, and allows users to override values read from the <i>braindump.txt</i> file. This option has precedence over the properties file specified in the <i>braindump.txt</i> file. Please note that these properties will apply not only to the main workflow, but also to all sub-workflows found.
--no-recursive	This options disables pegasus-monitor to automatically follow any sub-workflows that are found.
--nodatabase , --no-database , --no-events	Turns off generating events (when this option is given, pegasus-monitor will only generate the <i>jobstate.log</i> file). The default is to automatically log information to a SQLite database (see the --dest option below for more details). This option overrides any parameter given by the --dest option.
-r , --replay	This option is used to replay the output of an already finished workflow. It should only be used after the workflow is finished (not necessarily successfully). If a <i>jobstate.log</i> file is found, it will be rotated. However, when using a database, all previous references to that workflow (and all its sub-workflows) will be erased from it. When outputting to a bp file, the file will be deleted. When running in replay mode, pegasus-monitor will always run with the --no-daemon option, and any errors will be output directly to the terminal. Also, pegasus-monitor will not process any notifications while in replay mode.
--no-notifications	This options disables notifications completely, making pegasus-monitor ignore all the <i>.notify</i> files for all workflows it tracks.
--notifications-max <i>max_notifications</i>	This option sets the maximum number of concurrent notifications that pegasus-monitor will start. When the <i>max_notifications</i> limit is reached, pegasus-monitor will queue notifications and wait for a pending notification script to finish before starting a new one. If <i>max_notifications</i> is set to 0, notifications will be disabled.
--notifications-timeout <i>timeout</i>	Normally, pegasus-monitor will start a notification script and wait indefinitely for it to finish. This option allows users to set up a maximum <i>timeout</i> that pegasus-monitor will wait for a notification script to finish before terminating it. If notification scripts do not finish in a reasonable amount of time, it can cause other notification scripts to be queued due to the maximum number of concurrent scripts allowed by pegasus-monitor . Additionally, until all notification scripts finish, pegasus-monitor will not terminate.
-s <i>millisleep</i> , --sim <i>millisleep</i>	This option simulates delays between reads, by sleeping <i>millisleep</i> milliseconds. This option is mainly used by developers.
--db-stats	This option causes the database module to collect and print database statistics at the end of the execution. It has no effect if the --no-database option is given.
--skip-stdout	This option causes pegasus-monitor not to populate jobs' stdout and stderr into the BP file or the Stampede database. It should be used to avoid increasing the database size substantially in cases where jobs are very verbose in their output.
-f , --force	This option causes pegasus-monitor to skip checking for another instance of itself already running on the same workflow directory. The default behavior prevents two or more pegasus-monitor instances from starting and running simultaneously (which would cause the bp file and database to be left in an unstable state). This option should not be used when the user knows the previous instance of pegasus-monitor is NOT running anymore.
--socket	This option causes pegasus-monitor to start a socket interface that can be used for advanced debugging. The port number for connecting to pegasus-monitor can be found in the <i>monitor.sock</i> file in the workflow directory (the file is deleted when pegasus-monitor finishes). If not already started,

	the socket interface is also created when pegasus-monitor receives a <i>USR1</i> signal.
-o <i>dir</i> , --output-dir <i>dir</i>	When this option is given, pegasus-monitor will create all its output files in the directory specified by <i>dir</i> . This option is useful for allowing a user to debug a workflow in a directory the user does not have write permissions. In this case, all files generated by pegasus-monitor will have the workflow <i>wf_uuid</i> as a prefix so that files from multiple sub-workflows can be placed in the same directory. This option is mainly used by pegasus-analyzer . It is important to note that the location for the output BP file or database is not changed by this option and should be set via the --dest option.
-d <i>URL params</i> , --dest <i>URL params</i>	This option allows users to specify the destination for the log events generated by pegasus-monitor . If this option is omitted, pegasus-monitor will create a SQLite database in the workflow's run directory with the same name as the workflow, but with a <i>.stampede.db</i> prefix. For an <i>empty</i> scheme, <i>params</i> are a file path with <i>-</i> meaning standard output. For a <i>x-tcp</i> scheme, <i>params</i> are <i>TCP_host[:port=14380]</i> . For a database scheme, <i>params</i> are a <i>SQLAlchemy engine URL</i> with a database connection string that can be used to specify different database engines. Please see the examples section below for more information on how to use this option. Note that when using a database engine other than sqlite , the necessary Python database drivers will need to be installed.
-e <i>encoding</i> , --encoding <i>encoding</i>	This option specifies how to encode log events. The two available possibilities are <i>bp</i> and <i>bson</i> . If this option is not specified, events will be generated in the <i>bp</i> format.
<i>DAGMan_output_file</i>	The <i>DAGMan_output_file</i> is the only requires command-line argument in pegasus-monitor and must have the <i>.dag.dagman.out</i> extension.

Return Value

If the plan could be constructed, **pegasus-monitor** returns with an exit code of 0. However, in case of error, a non-zero exit code indicates problems. In that case, the *logfile* should contain additional information about the error condition.

Environment Variables

pegasus-monitor does not require that any environmental variables be set. It locates its required Python modules based on its own location, and therefore should not be moved outside of Pegasus' bin directory.

Examples

Usually, **pegasus-monitor** is invoked automatically by **pegasus-run** and tracks the workflow progress in real-time, producing the *jobstate.log* file and a corresponding SQLite database. When a workflow fails, and is re-submitted with a rescue DAG, **pegasus-monitor** will automatically pick up from where it left previously and continue the *jobstate.log* file and the database.

If users need to create the *jobstate.log* file after a workflow is already finished, the **--replay | -r** option should be used when running **pegasus-monitor** manually. For example:

```
$ pegasus_monitor -r diamond-0.dag.dagman.out
```

will launch **pegasus-monitor** in replay mode. In this case, if a *jobstate.log* file already exists, it will be rotated and a new file will be created. If a *diamond-0.stampede.db* SQLite database already exists, **pegasus-monitor** will purge all references to the workflow id specified in the *braindump.txt* file, including all sub-workflows associated with that workflow id.

```
$ pegasus_monitor -r --no-database diamond-0.dag.dagman.out
```

will do the same thing, but without generating any log events.

```
$ pegasus_monitor -r --dest `pwd`/diamond-0.bp diamond-0.dag.dagman.out
```

will create the file *diamond-0.bp* in the current directory, containing NetLogger events with all the workflow data. This is in addition to the *jobstate.log* file.

For using a database, users should provide a database connection string in the format of:

```
dialect://username:password@host:port/database
```

Where *dialect* is the name of the underlying driver (*mysql*, *sqlite*, *oracle*, *postgres*) and *database* is the name of the database running on the server at the *host* computer.

If users want to use a different *SQLite* database, **pegasus-monitord** requires them to specify the absolute path of the alternate file. For example:

```
$ pegasus_monitord -r --dest sqlite:///home/user/diamond_database.db diamond-0.dag.dagman.out
```

Here are docs with details for all of the supported drivers: <http://www.sqlalchemy.org/docs/05/reference/dialects/index.html>

Additional per-database options that work into the connection strings are outlined there.

It is important to note that one will need to have the appropriate db interface library installed. Which is to say, *SQLAlchemy* is a wrapper around the *mysql* interface library (for instance), it does not provide a *MySQL* driver itself. The **Pegasus** distribution includes both **SQLAlchemy** and the **SQLite** Python driver.

As a final note, it is important to mention that unlike when using *SQLite* databases, using **SQLAlchemy** with other database servers, e.g. *MySQL* or *Postgres*, the target database needs to exist. So, if a user wanted to connect to:

```
mysql://pegasus-user:supersecret@localhost:localport/diamond
```

it would need to first connect to the server at *localhost* and issue the appropriate create database command before running **pegasus-monitord** as **SQLAlchemy** will take care of creating the tables and indexes if they do not already exist.

Name

pegasus-mpi-cluster — a tool for running computational workflows expressed as DAGs (Directed Acyclic Graphs) on computational clusters using MPI.

Synopsis

pegasus-mpi-cluster [options] *workflow.dag*

Description

pegasus-mpi-cluster is a tool used to run HTC (High Throughput Computing) scientific workflows on systems designed for HPC (High Performance Computing). Many HPC systems have custom architectures that are optimized for tightly-coupled, parallel applications. These systems commonly have exotic, low-latency networks that are designed for passing short messages very quickly between compute nodes. Many of these networks are so highly optimized that the compute nodes do not even support a TCP/IP stack. This makes it impossible to run HTC applications using software that was designed for commodity clusters, such as Condor.

pegasus-mpi-cluster was developed to enable loosely-coupled HTC applications such as scientific workflows to take advantage of HPC systems. In order to get around the network issues outlined above, **pegasus-mpi-cluster** uses MPI (Message Passing Interface), a commonly used API for writing SPMD (Single Process, Multiple Data) parallel applications. Most HPC systems have an MPI implementation that works on whatever exotic network architecture the system uses.

An **pegasus-mpi-cluster** job consists of a single master process (this process is rank 0 in MPI parlance) and several worker processes. The master process manages the workflow and assigns workflow tasks to workers for execution. The workers execute the tasks and return the results to the master. Any output written to stdout or stderr by the tasks is captured (see **TASK STUDIO**).

pegasus-mpi-cluster applications are expressed as DAGs (Directed Acyclic Graphs) (see **DAG FILES**). Each node in the graph represents a task, and the edges represent dependencies between the tasks that constrain the order in which the tasks are executed. Each task is a program and a set of parameters that need to be run (i.e. a command and some optional arguments). The dependencies typically represent data flow dependencies in the application, where the output files produced by one task are needed as inputs for another.

If an error occurs while executing a DAG that causes the workflow to stop, it can be restarted using a rescue file, which records the progress of the workflow (see **RESCUE FILES**). This enables **pegasus-mpi-cluster** to pick up running the workflow where it stopped.

pegasus-mpi-cluster was designed to work either as a standalone tool or as a complement to the Pegasus Workflow Management System (WMS). For more information about using PMC with Pegasus see the section on **PMC AND PEGASUS**.

pegasus-mpi-cluster allows applications expressed as a DAG to be executed in parallel on a large number of compute nodes. It is designed to be simple, lightweight and robust.

Options

-h , --help	Print help message
-V , --version	Print version information
-v , --verbose	Increase logging verbosity. Adding multiple -v increases the level more. The default log level is <i>INFO</i> . (see LOGGING)
-q , --quiet	Decrease logging verbosity. Adding multiple -q decreases the level more. The default log level is <i>INFO</i> . (see LOGGING)
-s , --skip-rescue	Ignore the rescue file for <i>workflow.dag</i> if it exists. Note that pegasus-mpi-cluster will still create a new rescue file for the current run. The default behavior is to use the rescue file if one is found. (see RESCUE FILES)
-o path , --stdout path	Path to file for task stdout. (see TASK STUDIO and --per-task-stdio)

-e <i>path</i> , --stderr <i>path</i>	Path to file for task stderr. (see TASK STUDIO and --per-task-stdio)
-m <i>M</i> , --max-failures <i>M</i>	Stop submitting new tasks after <i>M</i> tasks have failed. Once <i>M</i> has been reached, pegasus-mpi-cluster will finish running any tasks that have been started, but will not start any more tasks. This option is used to prevent pegasus-mpi-cluster from continuing to run a workflow that is suffering from a systematic error, such as a missing binary or an invalid path. The default for <i>M</i> is 0, which means unlimited failures are allowed.
-t <i>T</i> , --tries <i>T</i>	Attempt to run each task <i>T</i> times before marking the task as failed. Note that the <i>T</i> tries do not count as failures for the purposes of the -m option. A task is only considered failed if it is tried <i>T</i> times and all <i>T</i> attempts result in a non-zero exitcode. The value of <i>T</i> must be at least 1. The default is 1.
-n , --nolock	Do not lock DAGFILE. By default, pegasus-mpi-cluster will attempt to acquire an exclusive lock on DAGFILE to prevent multiple MPI jobs from running the same DAG at the same time. If this option is specified, then the lock will not be acquired.
-r , --rescue <i>path</i>	Path to rescue log. If the file exists, and -s is not specified, then the log will be used to recover the state of the workflow. The file is truncated after it is read and a new rescue log is created in its place. The default is to append <i>.rescue</i> to the DAG file name. (see RESCUE FILES)
--host-script <i>path</i>	Path to a script or executable to launch on each unique host that pegasus-mpi-cluster is running on. This path can also be set using the <code>PMC_HOST_SCRIPT</code> environment variable. (see HOST SCRIPTS)
--host-memory <i>size</i>	Amount of memory available on each host in MB. The default is to determine the amount of physical RAM automatically. This value can also be set using the <code>PMC_HOST_MEMORY</code> environment variable. (see RESOURCE-BASED SCHEDULING)
--host-cpus <i>cpus</i>	Number of CPUs available on each host. The default is to determine the number of CPU cores automatically. This value can also be set using the <code>PMC_HOST_CPUS</code> environment variable. (see RESOURCE-BASED SCHEDULING)
--strict-limits	This enables strict memory usage limits for tasks. When this option is specified, and a task tries to allocate more memory than was requested in the DAG, the memory allocation operation will fail.
--max-wall-time <i>minutes</i>	This is the maximum number of minutes that pegasus-mpi-cluster will allow the workflow to run. When this time expires pegasus-mpi-cluster will abort the workflow and merge all of the stdout/stderr files of the workers. The value is in minutes, and the default is unlimited wall time. This option was added so that the output of a workflow will be recorded even if the workflow exceeds the max wall time of its batch job. This value can also be set using the <code>PMC_MAX_WALL_TIME</code> environment variable.
--per-task-stdio	This causes PMC to generate a <i>.out.XXX</i> and a <i>.err.XXX</i> file for each task instead of writing task stdout/stderr to --stdout and --stderr . The name of the files are "TASKNAME.out.XXX" and "TASKNAME.err.XXX", where "TASK-NAME" is the name of the task from the DAG and "XXX" is a sequence number that is incremented each time the task is tried. This option overrides the values for --stdout and --stderr . This argument is used by Pegasus when workflows are planned in PMC-only mode to facilitate debugging and monitoring.
--jobstate-log	This option causes PMC to generate a <i>jobstate.log</i> file for the workflow. The file is named "jobstate.log" and is placed in the same directory where the DAG file is located. If the file already exists, then PMC appends new lines to the existing file. This option is used by Pegasus when workflows are planned in PMC-only mode to facilitate monitoring.

--monitord-hack	This option causes PMC to generate a <code>.dagman.out</code> file for the workflow. This file mimics the contents of the <code>.dagman.out</code> file generated by Condor DAGMan. The point of this option is to trick monitord into thinking that it is dealing with DAGMan so that it will generate the appropriate events to populate the STAMPEDE database for monitoring purposes. The file is named "DAG.dagman.out" where "DAG" is the path to the PMC DAG file.
--no-resource-log	Do not generate a <code>workflow.dag.resource</code> file for the workflow.
--no-sleep-on-recv	Do not use polling with <code>sleep()</code> to implement message receive. (see Known Issues: CPU Usage)
--maxfds	Set the maximum number of file descriptors that can be left open by the master for I/O forwarding. By default this value is set automatically based on the value of <code>getrlimit(RLIMIT_NOFILE)</code> . The value must be at least 1, and cannot be more than <code>RLIMIT_NOFILE</code> .
--keep-affinity	By default PMC attempts to reset the CPU and memory affinity. This is to ensure that all available CPUs and memory can be used by PMC tasks on systems that are not configured properly. This flag tells PMC to keep the affinity settings inherited from its parent. Note that the memory policy can only be cleared if PMC was compiled with <code>libnuma</code> . CPU affinity is cleared using <code>sched_setaffinity()</code> , and memory policy is cleared with <code>set_mempolicy()</code> .

DAG Files

pegasus-mpi-cluster workflows are expressed using a simple text-based format similar to that used by Condor DAGMan. There are only two record types allowed in a DAG file: **TASK** and **EDGE**. Any blank lines in the DAG (lines with all whitespace characters) are ignored, as are any lines beginning with `#` (note that `#` can only appear at the beginning of a line, not in the middle).

The format of a **TASK** record is:

```
"TASK" id [options...] executable [arguments...]
```

Where *id* is the ID of the task, *options* is a list of task options, *executable* is the path to the executable or script to run, and *arguments...* is a space-separated list of arguments to pass to the task. An example is:

```
TASK t01 -m 10 -c 2 /bin/program -a -b
```

This example specifies a task *t01* that requires 10 MB memory and 2 CPUs to run */bin/program* with the arguments *-a* and *-b*. The available task options are:

-m M , --request-memory M	The amount of memory required by the task in MB. The default is 0, which means memory is not considered for this task. This option can be set for a job in the DAX by specifying the <code>pegasus::pmc_request_memory</code> profile. (see RESOURCE-BASED SCHEDULING)
-c N , --request-cpus N	The number of CPUs required by the task. The default is 1, which implies that the number of slots on a host should be less than or equal to the number of physical CPUs in order for all the slots to be used. This option can be set for a job in the DAX by specifying the <code>pegasus::pmc_request_cpus</code> profile. (see RESOURCE-BASED SCHEDULING)
-t T , --tries T	The number of times to try to execute the task before failing permanently. This is the task-level equivalent of the --tries command-line option.
-p P , --priority P	The priority of the task. P should be an integer. Larger values have higher priority. The default is 0. Priorities are simply hints and are not strict—if a task cannot be matched to an available slot (e.g. due to resource availability), but a lower-priority task can, then the task will be deferred and the lower priority task will be executed. This option can be set for a job in the DAX by specifying the <code>pegasus::pmc_priority</code> profile.

-f VAR=FILE , --pipe-forward
VAR=FILE

Forward I/O to file *FILE* using pipes to communicate with the task. The environment variable *VAR* will be set to the value of a file descriptor for a pipe to which the task can write to get data into *FILE*. For example, if a task specifies: `-f FOO=/tmp/foo` then the environment variable *FOO* for the task will be set to a number (e.g. 3) that represents the file `/tmp/foo`. In order to specify this argument in a Pegasus DAX you need to set the `pegasus::pmc_arguments` profile (note that the value of `pmc_arguments` must contain the `"-f"` part of the argument, so a valid value would be: `<profile namespace="pegasus" key="pmc_arguments">-f A=/tmp/a </profile>`). (see **I/O FORWARDING**)

-F SRC=DEST , --file-forward
SRC=DEST

Forward I/O to the file *DEST* from the file *SRC*. When the task finishes, the worker will read the data from *SRC* and send it to the master where it will be written to the file *DEST*. After *SRC* is read it is deleted. In order to specify this argument in a Pegasus DAX you need to set the `pegasus::pmc_arguments` profile. (see **I/O FORWARDING**)

The format of an **EDGE** record is:

```
"EDGE" parent child
```

Where *parent* is the ID of the parent task, and *child* is the ID of the child task. An example **EDGE** record is:

```
EDGE t01 t02
```

A simple diamond-shaped workflow would look like this:

```
# diamond.dag
TASK A /bin/echo "I am A"
TASK B /bin/echo "I am B"
TASK C /bin/echo "I am C"
TASK D /bin/echo "I am D"

EDGE A B
EDGE A C
EDGE B D
EDGE C D
```

Rescue Files

Many different types of errors can occur when running a DAG. One or more of the tasks may fail, the MPI job may run out of wall time, **pegasus-mpi-cluster** may segfault (we hope not), the system may crash, etc. In order to ensure that the DAG does not need to be restarted from the beginning after an error, **pegasus-mpi-cluster** generates a rescue file for each workflow.

The rescue file is a simple text file that lists all of the tasks in the workflow that have finished successfully. This file is updated each time a task finishes, and is flushed periodically so that if the workflow fails and the user restarts it, **pegasus-mpi-cluster** can determine which tasks still need to be executed. As such, the rescue file is a sort-of transaction log for the workflow.

The rescue file contains zero or more **DONE** records. The format of these records is:

```
"DONE" *taskid*
```

Where *taskid* is the ID of the task that finished successfully.

By default, rescue files are named *DAGNAME.rescue* where *DAGNAME* is the path to the input DAG file. The file name can be changed by specifying the **-r** argument.

PMC and Pegasus

Using PMC for Pegasus Task Clustering

PMC can be used as the wrapper for executing clustered jobs in Pegasus. In this mode Pegasus groups several tasks together and submits them as a single clustered job to a remote system. PMC then executes the individual tasks in the cluster and returns the results.

PMC can be specified as the task manager for clustered jobs in Pegasus in three ways:

1. Globally in the properties file

The user can set a property in the properties file that results in all the clustered jobs of the workflow being executed by PMC. In the Pegasus properties file specify:

```
#PEGASUS PROPERTIES FILE
pegasus.clusterer.job.aggregator=mpiexec
```

In the above example, all the clustered jobs on all remote sites will be launched via PMC as long as the property value is not overridden in the site catalog.

2. By setting the profile key "job.aggregator" in the site catalog:

```
<site handle="siteX" arch="x86" os="LINUX">
...
  <profile namespace="pegasus" key="job.aggregator">mpiexec</profile>
</site>
```

In the above example, all the clustered jobs on a siteX are going to be executed via PMC as long as the value is not overridden in the transformation catalog.

3. By setting the profile key "job.aggregator" in the transformation catalog:

```
tr B {
  site siteX {
    pfn "/path/to/mytask"
    arch "x86"
    os "linux"
    type "INSTALLED"
    profile pegasus "clusters.size" "3"
    profile pegasus "job.aggregator" "mpiexec"
  }
}
```

In the above example, all the clustered jobs for transformation B on siteX will be executed via PMC.

It is usually necessary to have a pegasus::mpiexec entry in your transformation catalog that specifies a) the path to PMC on the remote site and b) the relevant globus profiles such as xcount, host_xcount and maxwalltime to control size of the MPI job. That entry would look like this:

```
tr pegasus::mpiexec {
  site siteX {
    pfn "/path/to/pegasus-mpi-cluster"
    arch "x86"
    os "linux"
    type "INSTALLED"
    profile globus "maxwalltime" "240"
    profile globus "host_xcount" "1"
    profile globus "xcount" "32"
  }
}
```

If this transformation catalog entry is not specified, Pegasus will attempt create a default path on the basis of the environment profile PEGASUS_HOME specified in the site catalog for the remote site.

PMC can be used with both horizontal and label-based clustering in Pegasus, but we recommend using label-based clustering so that entire sub-graphs of a Pegasus DAX can be clustered into a single PMC job, instead of only a single level of the workflow.

Pegasus Profiles for PMC

There are several Pegasus profiles that map to PMC task options:

pmc_request_memory	This profile is used to set the --request-memory task option and is usually specified in the DAX or transformation catalog.
pmc_request_cpus	This key is used to set the --request-cpus task option and is usually specified in the DAX or transformation catalog.

pmc_priority This key is used to set the `--priority` task option and is usually specified in the DAX.

These profiles are used by Pegasus when generating PMC's input DAG when PMC is used as the task manager for clustered jobs in Pegasus.

The profiles can be specified in the DAX like this:

```
<job id="ID0000001" name="mytask">
  <arguments>-a 1 -b 2 -c 3</arguments>
  ...
  <profile namespace="pegasus" key="pmc_request_memory">1024</profile>
  <profile namespace="pegasus" key="pmc_request_cpus">4</profile>
  <profile namespace="pegasus" key="pmc_priority">10</profile>
</job>
```

This example specifies a PMC task that requires 1GB of memory and 4 cores, and has a priority of 10. It produces a task in the PMC DAG that looks like this:

```
TASK mytask_ID00000001 -m 1024 -c 4 -p 10 /path/to/mytask -a 1 -b 2 -c 3
```

Using PMC for the Entire Pegasus DAX

Pegasus can also be configured to run the entire workflow as a single PMC job. In this mode Pegasus will generate a single PMC DAG for the entire workflow as well as a PBS script that can be used to submit the workflow.

In contrast to using PMC as a task clustering tool, in this mode there are no jobs in the workflow executed without PMC. The entire workflow, including auxilliary jobs such as directory creation and file transfers, is managed by PMC. If Pegasus is configured in this mode, then DAGMan and Condor are not required.

To run in PMC-only mode, set the property "pegasus.code.generator" to "PMC" in the Pegasus properties file:

```
pegasus.code.generator=PMC
```

In order to submit the resulting PBS job you may need to make changes to the .pbs file generated by Pegasus to get it to work with your cluster. This mode is experimental and has not been used extensively.

Logging

By default, all logging messages are printed to stderr. If you turn up the logging using `-v` then you may end up with a lot of stderr being forwarded from the workers to the master.

The log levels in order of severity are: FATAL, ERROR, WARN, INFO, DEBUG, and TRACE.

The default logging level is INFO. The logging levels can be increased with `-v` and decreased with `-q`.

Task STDIO

By default the stdout and stderr of tasks will be redirected to the master's stdout and stderr. You can change the path of these files with the `-o` and `-e` arguments. You can also enable per-task stdio files using the `--per-task-stdio` argument. Note that if per-task stdio files are not used then the stdio of all workers will be merged into one out and one err file by the master at the end, so I/O from different workers will not be interleaved, but I/O from each worker will appear in the order that it was generated. Also note that, if the job fails for any reason, the outputs will not be merged, but instead there will be one file for each worker named DAGFILE.out.X and DAGFILE.err.X, where DAGFILE is the path to the input DAG, and X is the worker's rank.

Host Scripts

A host script is a shell script or executable that **pegasus-mpi-cluster** launches on each unique host on which it is running. They can be used to start auxilliary services, such as memcached, that the tasks in a workflow require.

Host scripts are specified using either the `--host-script` argument or the `PMC_HOST_SCRIPT` environment variable.

The host script is started when **pegasus-mpi-cluster** starts and must exit with an exitcode of 0 before any tasks can be executed. If it the host script returns a non-zero exitcode, then the workflow is aborted. The host script is given 60

seconds to do any setup that is required. If it doesn't exit in 60 seconds then a `SIGALRM` signal is delivered to the process, which, if not handled, will cause the process to terminate.

When the workflow finishes, **pegasus-mpi-cluster** will deliver a `SIGTERM` signal to the host script's process group. Any child processes left running by the host script will receive this signal unless they created their own process group. If there were any processes left to receive this signal, then they will be given a few seconds to exit, then they will be sent `SIGKILL`. This is the mechanism by which processes started by the host script can be informed of the termination of the workflow.

Resource-Based Scheduling

High-performance computing resources often have a low ratio of memory to CPUs. At the same time, workflow tasks often have high memory requirements. Often, the memory requirements of a workflow task exceed the amount of memory available to each CPU on a given host. As a result, it may be necessary to disable some CPUs in order to free up enough memory to run the tasks. Similarly, many codes have support for multicore hosts. In that case it is necessary for efficiency to ensure that the number of cores required by the tasks running on a host do not exceed the number of cores available on that host.

In order to make this process more efficient, **pegasus-mpi-cluster** supports resource-based scheduling. In resource-based scheduling the tasks in the workflow can specify how much memory and how many CPUs they require, and **pegasus-mpi-cluster** will schedule them so that the tasks running on a given host do not exceed the amount of physical memory and CPUs available. This enables **pegasus-mpi-cluster** to take advantage of all the CPUs available when the tasks' memory requirement is low, but also disable some CPUs when the tasks' memory requirement is higher. It also enables workflows with a mixture of single core and multi-core tasks to be executed on a heterogeneous pool.

If there are no hosts available that have enough memory and CPUs to execute one of the tasks in a workflow, then the workflow is aborted.

Memory

Users can specify both the amount of memory required per task, and the amount of memory available per host. If the amount of memory required by any task exceeds the available memory of all the hosts, then the workflow will be aborted. By default, the host memory is determined automatically, however the user can specify `--host-memory` to "lie" to **pegasus-mpi-cluster**. The amount of memory required for each task is specified in the DAG using the `-m/--request-memory` argument (see **DAG Files**).

CPUs

Users can specify the number of CPUs required per task, and the total number of CPUs available on each host. If the number of CPUs required by a task exceeds the available CPUs on all hosts, then the workflow will be aborted. By default, the number of CPUs on a host is determined automatically, but the user can specify `--host-cpus` to over- or under-subscribe the host. The number of CPUs required for each task is specified in the DAG using the `-c/--request-cpus` argument (see **DAG Files**).

I/O Forwarding

In workflows that have lots of small tasks it is common for the I/O written by those tasks to be very small. For example, a workflow may have 10,000 tasks that each write a few KB of data. Typically each task writes to its own file, resulting in 10,000 files. This I/O pattern is very inefficient on many parallel file systems because it requires the file system to handle a large number of metadata operations, which are a bottleneck in many parallel file systems.

One way to handle this problem is to have all 10,000 tasks write to a single file. The problem with this approach is that it requires those tasks to synchronize their access to the file using POSIX locks or some other mutual exclusion mechanism. Otherwise, the writes from different tasks may be interleaved in arbitrary order, resulting in unusable data.

In order to address this use case PMC implements a feature that we call "I/O Forwarding". I/O forwarding enables each task in a PMC job to write data to an arbitrary number of shared files in a safe way. It does this by having PMC worker processes collect data written by the task and send it over the high-speed network using MPI messaging to the PMC master process, where it is written to the output file. By having one process (the PMC master process) write to the file all of the I/O from many parallel tasks can be synchronized and written out to the files safely.

There are two different ways to use I/O forwarding in PMC: pipes and files. Pipes are more efficient, but files are easier to use.

I/O forwarding using pipes

I/O forwarding with pipes works by having PMC worker processes collect data from each task using UNIX pipes. This approach is more efficient than the file-based approach, but it requires the code of the task to be changed so that the task writes to the pipe instead of a regular file.

In order to use I/O forwarding a PMC task just needs to specify the **-f/--pipe-forward** argument to specify the name of the file to forward data to, and the name of an environment variable through which the PMC worker process can inform it of the file descriptor for the pipe.

For example, if there is a task "mytask" that needs to forward data to two files: "myfile.a" and "myfile.b", it would look like this:

```
TASK mytask -f A=/tmp/myfile.a -f B=/tmp/myfile.b /bin/mytask
```

When the /bin/mytask process starts it will have two variables in its environment: "A=3" and "B=4", for example. The value of these variables is the file descriptor number of the corresponding files. In this case, if the task wants to write to "/tmp/myfile.a", it gets the value of environment variable "A", and calls write() on that descriptor number. In C the code for that looks like this:

```
char *A = getenv("A");
int fd = atoi(A);
char *message = "Hello, World\n";
write(fd, message, strlen(message));
```

In some programming languages it is not possible to write to a file descriptor directly. Fortran, for example, refers to files by unit number instead of using file descriptors. In these languages you can either link C I/O functions into your binary and call them from routines written in the other language, or you can open a special file in the Linux /proc file system to get another handle to the pipe you want to access. For the latter, the file you should open is "/proc/self/fd/NUMBER" where NUMBER is the file descriptor number you got from the environment variable. For the example above, the pipe for myfile.a (environment variable A) is "/proc/self/fd/3".

If you are using **pegasus-kickstart**, which is probably the case if you are using PMC for a Pegasus workflow, then there's a trick you can do to avoid modifying your code. You use the /proc file system, as described above, but you let pegasus-kickstart handle the path construction. For example, if your application has an argument, -o, that allows you to specify the output file then you can write your task like this:

```
TASK mytask -f A=/tmp/myfile.a /bin/pegasus-kickstart /bin/mytask -o /proc/self/fd/$A
```

In this case, pegasus-kickstart will replace the \$A in your application arguments with the file descriptor number you want. Your code can open that path normally, write to it, and then close it as if it were a regular file.

I/O forwarding using files

I/O forwarding with files works by having tasks write out data in files on the local disk. The PMC worker process reads these files and forwards the data to the master where it can be written to the desired output file. This approach may be much less efficient than using pipes because it involves the file system, which has more overhead than a pipe.

File forwarding can be enabled by giving the **-F/--file-forward** argument to a task.

Here's an example:

```
TASK mytask -F /tmp/foo.0=/scratch/foo /bin/mytask -o /tmp/foo.0
```

In this case, the worker process will expect to find the file /tmp/foo.0 when mytask exits successfully. It reads the data from that file and sends it to the master to be written to the end of /scratch/foo. After /tmp/foo.0 is read it will be deleted by the worker process.

This approach works best on systems where the local disk is a RAM file system such as Cray XT machines. Alternatively, the task can use /dev/shm on a regular Linux cluster. It might also work relatively efficiently on a local disk if the file system cache is able to absorb all of the reads and writes.

I/O forwarding caveats

When using I/O forwarding it is important to consider a few caveats.

First, if the PMC job fails for any reason (including when the workflow is aborted for violating **--max-wall-time**), then the files containing forwarded I/O may be corrupted. They can include **partial records**, meaning that only part of the I/O from one or more tasks was written, and they can include **duplicate records**, meaning that the I/O was written, but the PMC job failed before the task could be marked as successful, and the workflow was restarted later. We make no guarantees about the contents of the data files in this case. It is up to the code that reads the files to a) detect and b) recover from such problems. To eliminate duplicates the records should include a unique identifier, and to eliminate partials the records should include a checksum.

Second, you should not use I/O forwarding if your task is going to write a lot of data to the file. Because the PMC worker is reading data off the pipe/file into memory and sending it in an MPI message, if you write too much, then the worker process will run the system out of memory. Also, all the data needs to fit in a single MPI message. In pipe forwarding there is no hard limit on the size, but in file forwarding the limit is 1MB. We haven't benchmarked the performance on large I/O, but anything larger than about 1 MB is probably too much. At any rate, if your data is larger than 1MB, then I/O forwarding probably won't have much of a performance benefit anyway.

Third, the I/O is not written to the file if the task returns a non-zero exitcode. We assume that if the task failed that you don't want the data it produced.

Fourth, the data from different tasks is not interleaved. All of the data written by a given task will appear sequentially in the output file. Note that you can still get partial records, however, if any data from a task appears it will never be split among non-adjacent ranges in the output file. If you have 3 tasks that write: "I am a task" you can get:

```
I am a taskI am a taskI am a task
```

and:

```
I am a taskI amI am a task
```

but not:

```
I am a taskI amI am a task a task
```

Fifth, data from different tasks appears in arbitrary order in the output file. It depends on what order the tasks were executed by PMC, which may be arbitrary if there are no dependencies between the tasks. The data that is written should contain enough information that you are able to determine which task produced it if you require that. PMC does not add any headers or trailers to the data.

Sixth, a task will only be marked as successful if all of its I/O was successfully written. If the workflow completed successfully, then the I/O is guaranteed to have been written.

Seventh, if the master is not able to write to the output file for any reason (e.g. the master tries to write the I/O to the destination file, but the write() call returns an error) then the task is marked as failed even if the task produced a non-zero exitcode. In other words, you may get a non-zero kickstart record even when PMC marks the task failed.

Eighth, the pipes are write-only. If you need to read and write data from the file you should use file forwarding and not pipe forwarding.

Ninth, all files are opened by the master in append mode. This is so that, if the workflow fails and has to be restarted, or if a task fails and is retried, the data that was written previously is not lost. PMC never truncates the files. This is one of the reasons why you can have partial records and duplicate records in the output file.

Finally, in file forwarding the output file is removed when the task exits. You cannot rely on the file to be there when the next task runs even if you write it to a shared file system.

Misc

Resource Utilization

At the end of the workflow run, the master will report the resource utilization of the job. This is done by adding up the total runtimes of all the tasks executed (including failed tasks) and dividing by the total wall time of the job times

N, where N is both the total number of processes including the master, and the total number of workers. These two resource utilization values are provided so that users can get an idea about how efficiently they are making use of the resources they allocated. Low resource utilization values suggest that the user should use fewer cores, and longer wall time, on future runs, while high resource utilization values suggest that the user could use more cores for future runs and get a shorter wall time.

Known Issues

fork() and exec()

In order for the worker processes to start tasks on the compute node the compute nodes must support the **fork()** and **exec()** system calls. If your target machine runs a stripped-down OS on the compute nodes that does not support these system calls, then **pegasus-mpi-cluster** will not work.

CPU Usage

Many MPI implementations are optimized so that message sends and receives do busy waiting (i.e. they spin/poll on a message send or receive instead of sleeping). The reasoning is that sleeping adds overhead and, since many HPC systems use space sharing on dedicated hardware, there are no other processes competing, so spinning instead of sleeping can produce better performance. On those implementations MPI processes will run at 100% CPU usage even when they are just waiting for a message. This is a big problem for multicore tasks in **pegasus-mpi-cluster** because idle slots consume CPU resources. In order to solve this problem **pegasus-mpi-cluster** processes sleep for a short period between checks for waiting messages. This reduces the load significantly, but causes a short delay in receiving messages. If you are using an MPI implementation that sleeps on message send and receive instead of doing busy waiting, then you can disable the sleep by specifying the **--no-sleep-on-recv** option. Note that the master will always sleep if **--max-wall-time** is specified because there is no way to interrupt or otherwise timeout a blocking call in MPI (e.g. SIGALRM does not cause MPI_Recv to return EINTR).

Environment Variables

The environment variables below are aliases for command-line options. If the environment variable is present, then it is used as the default for the associated option. If both are present, then the command-line option is used.

PMC_HOST_SCRIPT Alias for the **--host-script** option.

PMC_HOST_MEMORY Alias for the **--host-memory** option.

PMC_HOST_CPUS Alias for the **--host-cpus** option.

PMC_MAX_WALL_TIME Alias for the **--max-wall-time** option.

Name

pegasus-plan — runs Pegasus to generate the executable workflow

Synopsis

```
pegasus-plan [-v] [-q] [-V] [-h]
              [-Dprop=value...] [-b prefix]
              [--conf propsfile]
              [-c cachefile[,cachefile...]]
              [-C style[,style...]]
              [--dir dir]
              [--force] [--force-replan]
              [--inherited-rc-files] [-j prefix]
              [-n][--I input-dir][--O output-dir] [--o site]
              [-s site1[,site2...]]
              [--staging-site s1=ss1[,s2=ss2[...]]]
              [--randomdir[=dirname]]
              [--relative-dir dir]
              [--relative-submit-dir dir]
              -d daxfile
```

Description

The **pegasus-plan** command takes in as input the DAX and generates an executable workflow usually in form of **condor** submit files, which can be submitted to an *execution* site for execution.

As part of generating an executable workflow, the planner needs to discover:

data	<p>The Pegasus Workflow Planner ensures that all the data required for the execution of the executable workflow is transferred to the execution site by adding transfer nodes at appropriate points in the DAG. This is done by looking up an appropriate Replica Catalog to determine the locations of the input files for the various jobs. At present the default replica mechanism used is RLS.</p> <p>The Pegasus Workflow Planner also tries to reduce the workflow, unless specified otherwise. This is done by deleting the jobs whose output files have been found in some location in the Replica Catalog. At present no cost metrics are used. However preference is given to a location corresponding to the execution site</p> <p>The planner can also add nodes to transfer all the materialized files to an output site. The location on the output site is determined by looking up the site catalog file, the path to which is picked up from the pegasus.catalog.site.file property value.</p>
executables	<p>The planner looks up a Transformation Catalog to discover locations of the executables referred to in the executable workflow. Users can specify INSTALLED or STAGEABLE executables in the catalog. Stageable executables can be used by Pegasus to stage executables to resources where they are not pre-installed.</p>
resources	<p>The layout of the sites, where Pegasus can schedule jobs of a workflow are described in the Site Catalog. The planner looks up the site catalog to determine for a site what directories a job can be executed in, what servers to use for staging in and out data and what jobmanagers (if applicable) can be used for submitting jobs.</p>

The data and executable locations can now be specified in DAX'es conforming to DAX schema version 3.2 or higher.

Options

Any option will be displayed with its long options synonym(s).

-Dproperty=value

The **-D** option allows an experienced user to override certain properties which influence the program execution, among them the default location of the user's

properties file and the PEGASUS home location. One may set several CLI properties by giving this option multiple times. The **-D** option(s) must be the first option on the command line. A CLI property take precedence over the properties file property of the same key.

-d file , **--dax file**

The DAX is the XML input file that describes an abstract workflow. This is a mandatory option, which has to be used.

-b prefix , **--basename prefix**

The basename prefix to be used while constructing per workflow files like the dagman file (.dag file) and other workflow specific files that are created by Condor. Usually this prefix, is taken from the name attribute specified in the root element of the dax files.

-c file[,file,...] , **--cache file[,file,...]**

A comma separated list of paths to replica cache files that override the results from the replica catalog for a particular LFN.

Each entry in the cache file describes a LFN , the corresponding PFN and the associated attributes. The pool attribute should be specified for each entry.

```
LFN_1 PFN_1 pool=[site handle 1]
LFN_2 PFN_2 pool=[site handle 2]
...
LFN_N PFN_N [site handle N]
```

To treat the cache files as supplemental replica catalogs set the property **pegasus.catalog.replica.cache.asrc** to true. This results in the mapping in the cache files to be merged with the mappings in the replica catalog. Thus, for a particular LFN both the entries in the cache file and replica catalog are available for replica selection.

-C style[,style,...] , **--cluster style[,style,...]**

Comma-separated list of clustering styles to apply to the workflow. This mode of operation results in clustering of n compute jobs into a larger jobs to reduce remote scheduling overhead. You can specify a list of clustering techniques to recursively apply them to the workflow. For example, this allows you to cluster some jobs in the workflow using horizontal clustering and then use label based clustering on the intermediate workflow to do vertical clustering.

The clustered jobs can be run at the remote site, either sequentially or by using MPI. This can be specified by setting the property **pegasus.job.aggregator**. The property can be overridden by associating the PEGASUS profile key *collapser* either with the transformation in the transformation catalog or the execution site in the site catalog. The value specified (to the property or the profile), is the logical name of the transformation that is to be used for clustering jobs. Note that clustering will only happen if the corresponding transformations are catalogued in the transformation catalog.

PEGASUS ships with a clustering executable *pegasus-cluster* that can be found in the *\$PEGASUS_HOME/bin* directory. It runs the jobs in the clustered job sequentially on the same node at the remote site.

In addition, an MPI based clustering tool called *pegasus-mpi-cluster*, is also distributed and can be found in the bin directory. *pegasus-mpi-cluster* can also be used in the sharedfs setup and needs to be compiled against the remote site MPI install. directory. The wrapper is run on every MPI node, with the first one being the master and the rest of the ones as workers.

By default, *pegasus-cluster* is used for clustering jobs unless overridden in the properties or by the pegasus profile key *collapser*.

The following type of clustering styles are currently supported:

- **horizontal** is the style of clustering in which jobs on the same level are aggregated into larger jobs. A level of the workflow is defined as the greatest

distance of a node, from the root of the workflow. Clustering occurs only on jobs of the same type i.e they refer to the same logical transformation in the transformation catalog.

Horizontal Clustering can operate in one of two modes. a. Job count based.

The granularity of clustering can be specified by associating either the PEGASUS profile key *clusters.size* or the PEGASUS profile key *clusters.num* with the transformation.

The *clusters.size* key indicates how many jobs need to be clustered into the larger clustered job. The *clusters.num* key indicates how many clustered jobs are to be created for a particular level at a particular execution site. If both keys are specified for a particular transformation, then the *clusters.num* key value is used to determine the clustering granularity.

a. Runtime based.

To cluster jobs according to runtimes user needs to set one property and two profile keys. The property *pegasus.clusterer.preference* must be set to the value *runtime*. In addition user needs to specify two Pegasus profiles. a. *clusters.maxruntime* which specifies the maximum duration for which the clustered job should run for. b. *job.runtime* which specifies the duration for which the job with which the profile key is associated, runs for. Ideally, *clusters.maxruntime* should be set in transformation catalog and *job.runtime* should be set for each job individually.

- **label** is the style of clustering in which you can label the jobs in your workflow. The jobs with the same level are put in the same clustered job. This allows you to aggregate jobs across levels, or in a manner that is best suited to your application.

To label the workflow, you need to associate PEGASUS profiles with the jobs in the DAX. The profile key to use for labeling the workflow can be set by the property *pegasus.clusterer.label.key*. It defaults to *label*, meaning if you have a PEGASUS profile key *label* with jobs, the jobs with the same value for the pegasus profile key *label* will go into the same clustered job.

--conf *propfile*

The path to properties file that contains the properties planner needs to use while planning the workflow.

--dir *dir*

The base directory where you want the output of the Pegasus Workflow Planner usually condor submit files, to be generated. Pegasus creates a directory structure in this base directory on the basis of username, VO Group and the label of the workflow in the DAX.

By default the base directory is the directory from which one runs the **pegasus-plan** command.

-f , --force

This bypasses the reduction phase in which the abstract DAG is reduced, on the basis of the locations of the output files returned by the replica catalog. This is analogous to a **make** style generation of the executable workflow.

--force-replan

By default, for hierarichal workflows if a DAX job fails, then on job retry the rescue DAG of the associated workflow is submitted. This option causes Pegasus to replan the DAX job in case of failure instead.

-g , --group

The VO Group to which the user belongs to.

-h , --help

Displays all the options to the **pegasus-plan** command.

--inherited-rc-files *file[,file,...]*

A comma separated list of paths to replica files. Locations mentioned in these have a lower priority than the locations in the DAX file. This option is usu-

	ally used internally for hierarchical workflows, where the file locations mentioned in the parent (encompassing) workflow DAX, passed to the sub workflows (corresponding) to the DAX jobs.
-I , --input-dir	<p>A path to the input directory where the input files reside. This internally loads a Directory based Replica Catalog backend, that constructs does a directory listing to create the LFN#PFN mappings for the files in the input directory. You can specify additional properties either on the command line or the properties file to control the site attribute and url prefix associated with the mappings.</p> <p>pegasus.catalog.replica.directory.site specifies the pool attribute to associate with the mappings. Defaults to local</p> <p>pegasus.catalog.replica.directory.url.prefix specifies the URL prefix to use while constructing the PFN. Defaults to file://</p>
-j prefix , --job-prefix prefix	The job prefix to be applied for constructing the filenames for the job submit files.
-n , --nocleanup	<p>This results in the generation of the separate cleanup workflow that removes the directories created during the execution of the executable workflow. The cleanup workflow is to be submitted after the executable workflow has finished.</p> <p>If this option is not specified, then Pegasus adds cleanup nodes to the executable workflow itself that cleanup files on the remote sites when they are no longer required.</p>
-o site , --output-site site	<p>The output site to which the output files of the DAX are transferred to.</p> <p>By default the materialized data remains in the working directory on the execution site where it was created. Only those output files are transferred to an output site for which transfer attribute is set to true in the DAX.</p>
-O output directory , --output-dir output directory	<p>The output directory to which the output files of the DAX are transferred to.</p> <p>If -o is specified the storage directory of the site specified as the output site is updated to be the directory passed. If no output site is specified, then this option internally sets the output site to local with the storage directory updated to the directory passed.</p>
-q , --quiet	Decreases the logging level.
-r[dirname] , --randomdir[=dirname]	<p>Pegasus Workflow Planner adds create directory jobs to the executable workflow that create a directory in which all jobs for that workflow execute on a particular site. The directory created is in the working directory (specified in the site catalog with each site).</p> <p>By default, Pegasus duplicates the relative directory structure on the submit host on the remote site. The user can specify this option without arguments to create a random timestamp based name for the execution directory that are created by the create dir jobs. The user can specify the optional argument to this option to specify the basename of the directory that is to be created.</p> <p>The create dir jobs refer to the dirmanager executable that is shipped as part of the PEGASUS worker package. The transformation catalog is searched for the transformation named pegasus::dirmanager for all the remote sites where the workflow has been scheduled. Pegasus can create a default path for the dirmanager executable, if PEGASUS_HOME environment variable is associated with the sites in the site catalog as an environment profile.</p>
--relative-dir dir	The directory relative to the base directory where the executable workflow it to be generated and executed. This overrides the default directory structure that Pegasus creates based on username, VO Group and the DAX label.

--relative-submit-dir <i>dir</i>	The directory relative to the base directory where the executable workflow is to be generated. This overrides the default directory structure that Pegasus creates based on username, VO Group and the DAX label. By specifying --relative-dir and --relative-submit-dir you can have different relative execution directory on the remote site and different relative submit directory on the submit host.
-s <i>site[,site,...]</i> , --sites <i>site[,site,...]</i>	<p>A comma separated list of execution sites on which the workflow is to be executed. Each of the sites should have an entry in the site catalog, that is being used. To run on the submit host, specify the execution site as local.</p> <p>In case this option is not specified, all the sites in the site catalog are picked up as candidates for running the workflow.</p>
--staging-site <i>s1=ss1[,s2=ss2[...]]</i>	<p>A comma separated list of key=value pairs , where the key is the execution site and value is the staging site for that execution site.</p> <p>In case of running on a shared filesystem, the staging site is automatically associated by the planner to be the execution site. If only a value is specified, then that is taken to be the staging site for all the execution sites. e.g --staging-site local means that the planner will use the local site as the staging site for all jobs in the workflow.</p>
-s , --submit	Submits the generated executable workflow using pegasus-run script in \$PEGASUS_HOME/bin directory. By default, the Pegasus Workflow Planner only generates the Condor submit files and does not submit them.
-v , --verbose	<p>Increases the verbosity of messages about what is going on. By default, all FATAL, ERROR, CONSOLE and WARN messages are logged. The logging hierarchy is as follows:</p> <ol style="list-style-type: none">1. FATAL2. ERROR3. CONSOLE4. WARN5. INFO6. CONFIG7. DEBUG8. TRACE <p>For example, to see the INFO, CONFIG and DEBUG messages additionally, set -vvv.</p>
-V , --version	Displays the current version number of the Pegasus Workflow Management System.

Return Value

If the Pegasus Workflow Planner is able to generate an executable workflow successfully, the exitcode will be 0. All runtime errors result in an exitcode of 1. This is usually in the case when you have misconfigured your catalogs etc. In the case of an error occurring while loading a specific module implementation at run time, the exitcode will be 2. This is usually due to factory methods failing while loading a module. In case of any other error occurring during the running of the command, the exitcode will be 1. In most cases, the error message logged should give a clear indication as to where things went wrong.

Controlling pegasus-plan Memory Consumption

pegasus-plan will try to determine memory limits automatically using factors such as total system memory and potential memory limits (ulimits). The automatic limits can be overridden by setting the JAVA_HEAPMIN and JAVA_HEAPMAX environment variables before invoking pegasus-plan. The values are in megabytes. As a rule of thumb, JAVA_HEAPMIN can be set to half of the value of JAVA_HEAPMAX.

Pegasus Properties

This is not an exhaustive list of properties used. For the complete description and list of properties refer to [\\$PEGASUS_HOME/doc/advanced-properties.pdf](#)

pegasus.selector.site	Identifies what type of site selector you want to use. If not specified the default value of Random is used. Other supported modes are RoundRobin and Non-JavaCallout that calls out to a external site selector.
pegasus.catalog.replica	Specifies the type of replica catalog to be used. If not specified, then the value defaults to RLS .
pegasus.catalog.replica.url	Contact string to access the replica catalog. In case of RLS it is the RLI url.
pegasus.dir.exec	A suffix to the workdir in the site catalog to determine the current working directory. If relative, the value will be appended to the working directory from the site.config file. If absolute it constitutes the working directory.
pegasus.catalog.transformation	Specifies the type of transformation catalog to be used. One can use either a file based or a database based transformation catalog. At present the default is Text .
pegasus.catalog.transformation.file	The location of file to use as transformation catalog. If not specified, then the default location of \$PEGASUS_HOME/var/tc.data is used.
pegasus.catalog.site	Specifies the type of site catalog to be used. One can use either a text based or an xml based site catalog. At present the default is XML3 .
pegasus.catalog.site.file	The location of file to use as a site catalog. If not specified, then default value of \$PEGASUS_HOME/etc/sites.xml is used in case of the xml based site catalog and \$PEGASUS_HOME/etc/sites.txt in case of the text based site catalog.
pegasus.data.configuration	This property sets up Pegasus to run in different environments. This can be set to sharedfs If this is set, Pegasus will be setup to execute jobs on the shared filesystem on the execution site. This assumes, that the head node of a cluster and the worker nodes share a filesystem. The staging site in this case is the same as the execution site. nonsharedfs If this is set, Pegasus will be setup to execute jobs on an execution site without relying on a shared filesystem between the head node and the worker nodes. condorio If this is set, Pegasus will be setup to run jobs in a pure condor pool, with the nodes not sharing a filesystem. Data is staged to the compute nodes from the submit host using Condor File IO.
pegasus.code.generator	The code generator to use. By default, Condor submit files are generated for the executable workflow. Setting to Shell results in Pegasus generating a shell script that can be executed on the submit host.

Files

<code>\$PEGASUS_HOME/etc/dax-3.3.xsd</code>	is the suggested location of the latest DAX schema to produce DAX output.
<code>\$PEGASUS_HOME/etc/sc-3.0.xsd</code>	is the suggested location of the latest Site Catalog schema that is used to create the XML3 version of the site catalog
<code>\$PEGASUS_HOME/etc/tc.data.text</code>	is the suggested location for the file corresponding to the Transformation Catalog.
<code>\$PEGASUS_HOME/etc/sites.xml3 \$PEGASUS_HOME/etc/sites.xml</code>	is the suggested location for the file containing the site information.
<code>\$PEGASUS_HOME/lib/pegasus.jar</code>	contains all compiled Java bytecode to run the Pegasus Workflow Planner.

Name

pegasus-plots — A tool to generate graphs and charts to visualize workflow run.

Synopsis

```
pegasus-plots [-h|--help]
               [-o|--output outdir]
               [-c|--conf propfile]
               [-m|--max-graph-nodes max]
               [-p|--plotting-level level]
               [-i|--ignore-db-inconsistency]
               [-v|--verbose]
               [-q|--quiet]
               [submitdir]
```

Description

pegasus-plots generates graphs and charts to visualize workflow run. It generates workflow execution Gantt chart, job over time chart, time chart, dax and dag graph. It uses executable 'dot' to generate graphs. pegasus-plots looks for the executable in your path and generates graphs based on it's availability .

Options

-h , --help	Prints a usage summary with all the available command-line options.
-o <i>outdir</i> , --output <i>outdir</i>	Writes the output to the given directory
-c <i>propfile</i> , --conf <i>propfile</i>	The properties file to use. This option overrides all other property files.
-m <i>max</i> , --max-graph-nodes <i>max</i>	Maximum limit on the number of tasks/jobs in the dax/dag up to which the graph should be generated. The default value is 100.
-p <i>level</i> , --plotting-level <i>level</i>	Specifies the charts and graphs to generate. Valid levels are: all , all_charts , all_graphs , dax_graph , dag_graph , gantt_chart , host_chart , time_chart , breakdown_chart . Default is all_charts . The output generated by pegasus-plots is based on the <i>level</i> set: <ul style="list-style-type: none"> • all: generates all charts and graphs. • all_charts: generates all charts. • all_graphs: generates all graphs. • dax_graph: generates dax graph. • dag_graph: generates dag graph. • gantt_chart: generates the workflow execution Gantt chart. • host_chart: generates the host over time chart. • time_chart: generates the time chart which shows the job instance/invocation count and runtime over time. • breakdown_chart: generates the breakdown chart which shows the invocation count and runtime grouped by transformation name.
-i , --ignore-db-inconsistency	Turn off the the check for database consistency.
-v , --verbose	Increases the log level. If omitted, the default level will be set to WARNING. When this option is given, the log level is changed to INFO. If this option is repeated, the log level will be changed to DEBUG.

-q , --quiet

Decreases the log level. If omitted, the default level will be set to WARNING. When this option is given, the log level is changed to ERROR.

Example

Runs pegasus-plots and writes the output to the given directory:

```
pegasus-plots -o /scratch/plot /scratch/grid-setup/run0001
```

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-rc-client — shell client for replica implementations

Synopsis

```
pegasus-rc-client [-Dproperty=value[...]] [-V]
                  [-c fn] [-p k=v]
                  [[-f fn]][-i|-d fn][cmd [args]]
```

Description

The shell interface to replica catalog implementations is a prototype. It determines from various property setting which class implements the replica manager interface, and loads that driver at run-time. Some commands depend on the implementation.

Options

Any option will be displayed with its long options synonym(s).

-Dproperty=value The **-D** option allows an experienced user to override certain properties which influence the program execution, among them the default location of the user's properties file and the PEGASUS home location. One may set several CLI properties by giving this option multiple times. The **-D** option(s) must be the first option on the command line. A CLI property take precedence over the properties file property of the same key.

-c fn , **--conf fn** Path to the property file

-f fn , **--file fn** The optional input file argument permits to enter non-interactive bulk mode. If this option is not present, replica manager specific commands should be issued on the command-line. The special filename hyphen (-) can be used to read from pipes.

Default is to use an interactive interface reading from *stdin*.

-i fn , **--insert fn** The optional input file argument permits insertion of entries from the Replica Catalog in a bulk mode, wherever supported by the underlying implementation. This is highly, useful when interfacing with the Globus RLS as the backend, and one wants to insert millions of entries in it.

Each line in the file denotes one mapping of the format <lf> <pf> [k=v [..]]

-d fn , **--delete fn** The optional input file argument permits deletion of entries from the Replica Catalog in a bulk mode, wherever supported by the underlying implementation. This is highly, useful when interfacing with the Globus RLS as the backend, and one wants to delete millions of entries from it.

Each line in the file denotes one mapping of the format: <lf> <pf> [k=v [..]]

-p k=v , **--pref k=v** This option may be specified multiple times. Each specification populates instance preferences. Preferences control the extend of log information, or the output format string to use in listings.

The keys **format** and **level** are recognized as of this writing.

There are no defaults.

cmd [args] If not in file-driven mode, a single command can be specified with its arguments.

Default is to use interactive mode.

-V , **--version** displays the version of Pegasus you are using.

Return Value

Regular and planned program terminations will result in an exit code of 0. Abnormal termination will result in a non-zero exit code.

Files

\$PEGASUS_HOME/etc/properties	contains the basic properties with all configurable options.
\$HOME/.pegasusrc	contains the basic properties with all configurable options.
pegasus.jar	contains all compiled Java bytecode to run the replica manager.

Environment Variables

PEGASUS_HOME	is the suggested base directory of your the execution environment.
JAVA_HOME	should be set and point to a valid location to start the intended Java virtual machine as <i>\$JAVA_HOME/bin/java</i> .
CLASSPATH	should be set to contain all necessary files for the execution environment. Please make sure that your <i>CLASSPATH</i> includes pointer to the replica implementation required jar files.

Properties

The complete branch of properties *pegasus.catalog.replica* including itself are interpreted by the prototype. While the *pegasus.catalog.replica* property itself steers the backend to connect to, any meaning of branched keys is dependent on the backend. The same key may have different meanings for different backends.

pegasus.catalog.replica	determines the name of the implementing class to load at run-time. If the class resides in <i>org.griphyn.common.catalog.replica</i> no prefix is required. Otherwise, the fully qualified class name must be specified.
pegasus.catalog.replica.url	is used by the RLS LRC implementations. It determines the RLI / LRC url to use.
pegasus.catalog.replica.file	is used by the SimpleFile implementation. It specifies the path to the file to use as the backend for the catalog.
pegasus.catalog.replica.db.driver	is used by a simple rDBMs implementation. The string is the fully-qualified class name of the JDBC driver used by the RDBMS implementer.
pegasus.catalog.replica.db.url	is the JDBC URL to use to connect to the database.
pegasus.catalog.replica.db.user	is used by a simple rDBMS implementation. It constitutes the database user account that contains the <i>RC_LFN</i> and <i>RC_ATTR</i> tables.
pegasus.catalog.replica.db.password	is used by a simple RDBMS implementation. It constitutes the database user account that contains the <i>RC_LFN</i> and <i>RC_ATTR</i> tables.
pegasus.catalog.replica.chunk.size	is used by the pegasus-rc-client for the bulk insert and delete operations. The value determines the number of lines that are read in at a time, and worked upon at together.

Commands

The command line tool provides a simplified shell-wrappable interface to manage a replica catalog backend. The commands can either be specified in a file in bulk mode, in a pipe, or as additional arguments to the invocation.

Note that you must escape special characters from the shell.

help	displays a small resume of the commands.
exit , quit	should only be used in interactive mode to exit the interactive mode.
clear	drops all contents from the backend. Use with special care!
insert <lfm> <pfn> [k=v [...]]	inserts a given lfm and pfn , and an optional site string into the backend. If the site is not specified, a <i>null</i> value is inserted for the site .
delete <lfm> <pfn> [k=v [...]]	removes a triple of lfm , pfn and, optionally, site from the replica backend. If the site was not specified, all matches of the lfm pfn pairs will be removed, regardless of the site .
lookup <lfm> [<lfm> [...]]	retrieves one or more mappings for a given lfm from the replica backend.
remove <lfm> [<lfm> [...]]	removes all mappings for each lfm from the replica backend.
list [lfm <pat>] [pfn <pat>] [<name> <pat>]	obtains all matches from the replica backend. If no arguments were specified, all contents of the replica backend are matched. You must use the word lfm , pfn or <name> before specifying a pattern. The pattern is meaningful only to the implementation. Thus, a SQL implementation may chose to permit SQL wild-card characters. A memory-resident service may chose to interpret the pattern as regular expression.
set [var [value]]	sets an internal variable that controls the behavior of the front-end. With no arguments, all possible behaviors are displayed. With one argument, just the matching behavior is listed. With two arguments, the matching behavior is set to the value.

Database Schema

The tables are set up as part of the PEGASUS database setup. The files concerned with the database have a suffix *-rc.sql*.

Name

pegasus-remove — removes a workflow that has been planned and submitted using pegasus-plan and pegasus-run

Synopsis

pegasus-remove [-d *dagid*] [-v] [*rundir*]

Description

The pegasus-remove command remove a submitted/running workflow that has been planned and submitted using **pegasus-plan** and **pegasus-run**. The command can be invoked either in the planned directory with no options and arguments or just the full path to the run directory.

Options

By default pegasus-remove does not require any options or arguments if invoked from within the planned workflow directory. If running the command outside the workflow directory then a full path to the workflow directory needs to be specified or the *dagid* of the workflow to be removed.

pegasus-remove takes the following options:

-d <i>dagid</i> , --dagid <i>dagid</i>	The workflow dagid to remove
-v , --verbose	Raises debug level. Each invocation increase the level by 1.
<i>rundir</i>	Is the full qualified path to the base directory containing the planned workflow DAG and submit files. This is optional if pegasus-remove command is invoked from within the run directory.

Return Value

If the workflow is removed successfully pegasus-remove returns with an exit code of 0. However, in case of error, a non-zero exit code indicates problems. An error message clearly marks the cause.

Files

The following files are opened:

braindump	This file is located in the rundir. pegasus-remove uses this file to find out paths to several other files.
------------------	---

Environment Variables

PATH The path variable is used to locate binary for **condor_rm**.

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-run — executes a workflow that has been planned using **pegasus-plan**.

Synopsis

```
pegasus-run [-Dproperty=value...][-c propsfile][-d level]
              [-v][--grid*][rundir]
```

Description

The **pegasus-run** command executes a workflow that has been planned using **pegasus-plan**. By default **pegasus-run** can be invoked either in the planned directory with no options and arguments or just the full path to the run directory. **pegasus-run** also can be used to resubmit a failed workflow by running the same command again.

Options

By default **pegasus-run** does not require any options or arguments if invoked from within the planned workflow directory. If running the command outside the workflow directory then a full path to the workflow directory needs to be specified.

pegasus-run takes the following options

-Dproperty=value	The -D option allows an advanced user to override certain properties which influence pegasus-run . One may set several CLI properties by giving this option multiple times. The -D option(s) must be the first option on the command line. CLI properties take precedence over the file-based properties of the same key. See the PROPERTIES section below.
-c propsfile , --conf propsfile	Provide a property file to override the default Pegasus properties file from the planning directory. Ordinary users do not need to use this option unless the specifically want to override several properties
-d level , --debug level	Set the debug level for the client. Default is 0.
-v , --verbose	Raises debug level. Each invocation increase the level by 1.
--grid	Enable grid checks to see if your submit machine is GRID enabled.
rundir	Is the full qualified path to the base directory containing the planned workflow DAG and submit files. This is optional if the pegasus-run command is invoked from within the run directory.

Return Value

If the workflow is submitted for execution **pegasus-run** returns with an exit code of 0. However, in case of error, a non-zero return value indicates problems. An error message clearly marks the cause.

Files

The following files are created, opened or written to:

braindump	This file is located in the rundir. pegasus-run uses this file to find out paths to several other files, properties configurations etc.
pegasus.?????????.properties	This file is located in the rundir. pegasus-run uses this properties file by default to configure its internal settings.
workflowname.dag	pegasus-run uses the workflowname.dag or workflowname.sh file and submits it either to condor for execution or runs it locally in a shell environment

Properties

pegasus-run reads its properties from several locations.

RUNDIR/ pegasus.?????????.properties	The default location for pegasus-run to read the properties from
--conf propfile	properties file provided in the conf option replaces the default properties file used.
\$HOME/.pegasusrc	will be used if neither default rundir properties or --conf propertiesfile are found.

Additionally properties can be provided individually using the **-Dpropkey=propvalue** option on the command line before all other options. These properties will override properties provided using either **--conf** or *RUNDIR/pegasus.????????.properties* or the *\$HOME/.pegasusrc*

The merge logic is CONF PROPERTIES || DEFAULT RUNDIR PROPERTIES || PEGASUSRC overridden by Command line properties

Environment Variables

PATH The path variable is used to locate binaries for condor-submit-dag, condor-dagman, condor-submit, pegasus-submit-dag, pegasus-dagman and pegasus-monitord

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-s3 — Upload, download, delete objects in Amazon S3

Synopsis

```
pegasus-s3 help
pegasus-s3 ls [options] URL
pegasus-s3 mkdir [options] URL...
pegasus-s3 rmdir [options] URL...
pegasus-s3 rm [options] [URL...]
pegasus-s3 put [options] FILE URL
pegasus-s3 get [options] URL [FILE]
pegasus-s3 lsup [options] URL
pegasus-s3 rmup [options] URL [UPLOAD]
pegasus-s3 cp [options] SRC... DEST
```

Description

pegasus-s3 is a client for the Amazon S3 object storage service and any other storage services that conform to the Amazon S3 API, such as Eucalyptus Walrus.

Options

Global Options

-h , --help	Show help message for subcommand and exit
-d , --debug	Turn on debugging
-v , --verbose	Show progress messages
-C FILE , --conf=FILE	Path to configuration file

rm Options

-f , --force	If the URL does not exist, then ignore the error.
-F FILE , --file=FILE	File containing a list of URLs to delete

put Options

-c X , --chunksize=X	Set the chunk size for multipart uploads to X MB. A value of 0 disables multipart uploads. The default is 10MB, the min is 5MB and the max is 1024MB. This parameter only applies for sites that support multipart uploads (see <code>multipart_uploads</code> configuration parameter in the CONFIGURATION section). The maximum number of chunks is 10,000, so if you are uploading a large file, then the chunk size is automatically increased to enable the upload. Choose smaller values to reduce the impact of transient failures.
-p N , --parallel=N	Use N threads to upload <i>FILE</i> in parallel. The default value is 4, which enables parallel uploads with 4 threads. This parameter is only valid if the site supports multipart uploads and the --chunksize parameter is not 0. Otherwise parallel uploads are disabled.
-b , --create-bucket	Create the destination bucket if it does not already exist

get Options

-c X , --chunksize=X	Set the chunk size for parallel downloads to X megabytes. A value of 0 will avoid chunked reads. This option only applies for sites that support ranged downloads (see <code>ranged_downloads</code> configuration parameter). The default chunk size is 10MB, the min is
------------------------------------	---

1MB and the max is 1024MB. Choose smaller values to reduce the impact of transient failures.

-p *N* , --parallel=*N* Use *N* threads to upload FILE in parallel. The default value is 4, which enables parallel downloads with 4 threads. This parameter is only valid if the site supports ranged downloads and the **--chunksize** parameter is not 0. Otherwise parallel downloads are disabled.

rmup Options

-a , --all Cancel all uploads for the specified bucket

cp Options

-c , --create-dest Create the destination bucket if it does not exist.

-r , --recursive If SRC is a bucket, copy all of the keys in that bucket to DEST. In that case DEST must be a bucket.

-f , --force If DEST exists, then overwrite it.

Subcommands

pegasus-s3 has several subcommands for different storage service operations.

help The **help** subcommand lists all available subcommands.

ls The **ls** subcommand lists the contents of a URL. If the URL does not contain a bucket, then all the buckets owned by the user are listed. If the URL contains a bucket, but no key, then all the keys in the bucket are listed. If the URL contains a bucket and a key, then all keys in the bucket that begin with the specified key are listed.

mkdir The **mkdir** subcommand creates one or more buckets.

rmdir The **rmdir** subcommand deletes one or more buckets from the storage service. In order to delete a bucket, the bucket must be empty.

rm The **rm** subcommand deletes one or more keys from the storage service.

put The **put** subcommand stores the file specified by FILE in the storage service under the bucket and key specified by URL. If the URL contains a bucket, but not a key, then the file name is used as the key.

If a transient failure occurs, then the upload will be retried several times before **pegasus-s3** gives up and fails.

The **put** subcommand can do both chunked and parallel uploads if the service supports multipart uploads (see **multipart_uploads** in the **CONFIGURATION** section). Currently only Amazon S3 supports multipart uploads.

This subcommand will check the size of the file to make sure it can be stored before attempting to store it.

Chunked uploads are useful to reduce the probability of an upload failing. If an upload is chunked, then **pegasus-s3** issues separate PUT requests for each chunk of the file. Specifying smaller chunks (using **--chunksize**) will reduce the chances of an upload failing due to a transient error. Chunksizes can range from 5 MB to 1GB (chunk sizes smaller than 5 MB produced incomplete uploads on Amazon S3). The maximum number of chunks for any single file is 10,000, so if a large file is being uploaded with a small chunksize, then the chunksize will be increased to fit within the 10,000 chunk limit. By default, the file will be split into 10 MB chunks if the storage service supports multipart uploads. Chunked uploads can be disabled by specifying a chunksize of 0. If the upload is chunked, then each chunk is retried independently under transient failures. If any chunk fails permanently, then the upload is aborted.

Parallel uploads can increase performance for services that support multipart uploads. In a parallel upload the file is split into *N* chunks and each chunk is uploaded concurrently by one of *M* threads in first-come, first-served fashion. If the chunksize is set to 0, then parallel uploads are disabled. If *M* > *N*, then the

actual number of threads used will be reduced to N. The number of threads can be specified using the `--parallel` argument. If `--parallel` is 1, then only a single thread is used. The default value is 4. There is no maximum number of threads, but it is likely that the link will be saturated by 4 to 8 threads.

Under certain circumstances, when a multipart upload fails it could leave behind data on the server. When a failure occurs the **put** subcommand will attempt to abort the upload. If the upload cannot be aborted, then a partial upload may remain on the server. To check for partial uploads run the **lsup** subcommand. If you see an upload that failed in the output of **lsup**, then run the **rmup** subcommand to remove it.

get The **get** subcommand retrieves an object from the storage service identified by URL and stores it in the file specified by FILE. If FILE is not specified, then the key is used as the file name (Note: if the key has slashes, then the file name will be a relative subdirectory, but **pegasus-s3** will not create the subdirectory if it does not exist).

If a transient failure occurs, then the download will be retried several times before **pegasus-s3** gives up and fails.

The **get** subcommand can do both chunked and parallel downloads if the service supports ranged downloads (see **ranged_downloads** in the **CONFIGURATION** section). Currently only Amazon S3 has good support for ranged downloads. Eucalyptus Walrus supports ranged downloads, but the current release, 1.6, is inconsistent with the Amazon interface and has a bug that causes ranged downloads to hang in some cases. It is recommended that ranged downloads not be used with Eucalyptus until these issues are resolved.

Chunked downloads can be used to reduce the probability of a download failing. When a download is chunked, **pegasus-s3** issues separate GET requests for each chunk of the file. Specifying smaller chunks (using `--chunksize`) will reduce the chances that a download will fail to do a transient error. Chunk sizes can range from 1 MB to 1 GB. By default, a download will be split into 10 MB chunks if the site supports ranged downloads. Chunked downloads can be disabled by specifying a `--chunksize` of 0. If a download is chunked, then each chunk is retried independently under transient failures. If any chunk fails permanently, then the download is aborted.

Parallel downloads can increase performance for services that support ranged downloads. In a parallel download, the file to be retrieved is split into N chunks and each chunk is downloaded concurrently by one of M threads in a first-come, first-served fashion. If the chunksize is 0, then parallel downloads are disabled. If $M > N$, then the actual number of threads used will be reduced to N. The number of threads can be specified using the `--parallel` argument. If `--parallel` is 1, then only a single thread is used. The default value is 4. There is no maximum number of threads, but it is likely that the link will be saturated by 4 to 8 threads.

lsup The **lsup** subcommand lists active multipart uploads. The URL specified should point to a bucket. This command is only valid if the site supports multipart uploads. The output of this command is a list of keys and upload IDs.

This subcommand is used with **rmup** to help recover from failures of multipart uploads.

rmup The **rmup** subcommand cancels an active upload. The URL specified should point to a bucket, and UPLOAD is the long, complicated upload ID shown by the **lsup** subcommand.

This subcommand is used with **lsup** to recover from failures of multipart uploads.

cp The **cp** subcommand copies keys on the server. Keys cannot be copied between accounts.

URL Format

All URLs for objects stored in S3 should be specified in the following format:

```
s3[s]://USER@SITE[/BUCKET[/KEY]]
```

The protocol part can be `s3://` or `s3s://`. If `s3s://` is used, then **pegasus-s3** will force the connection to use SSL and override the setting in the configuration file. If `s3://` is used, then whether the connection uses SSL or not is determined by the value of the *endpoint* variable in the configuration for the site.

The *USER@SITE* part is required, but the *BUCKET* and *KEY* parts may be optional depending on the context.

The *USER@SITE* portion is referred to as the “identity”, and the *SITE* portion is referred to as the “site”. Both the identity and the site are looked up in the configuration file (see **CONFIGURATION**) to determine the parameters to use when establishing a connection to the service. The site portion is used to find the host and port, whether to use SSL, and other things. The identity portion is used to determine which authentication tokens to use. This format is designed to enable users to easily use multiple services with multiple authentication tokens. Note that neither the *USER* nor the *SITE* portion of the URL have any meaning outside of **pegasus-s3**. They do not refer to real usernames or hostnames, but are rather handles used to look up configuration values in the configuration file.

The *BUCKET* portion of the URL is the part between the 3rd and 4th slashes. Buckets are part of a global namespace that is shared with other users of the storage service. As such, they should be unique.

The *KEY* portion of the URL is anything after the 4th slash. Keys can include slashes, but S3-like storage services do not have the concept of a directory like regular file systems. Instead, keys are treated like opaque identifiers for individual objects. So, for example, the keys *a/b* and *a/c* have a common prefix, but cannot be said to be in the same *directory*.

Some example URLs are:

```
s3://ewa@amazon
s3://juve@skynet/gideon.isi.edu
s3://juve@magellan/pegasus-images/centos-5.5-x86_64-20101101.part.1
s3s://ewa@amazon/pegasus-images/data.tar.gz
```

Configuration

Each user should specify a configuration file that **pegasus-s3** will use to look up connection parameters and authentication tokens.

Search Path

This client will look in the following locations, in order, to locate the user’s configuration file:

1. The `-C/--conf` argument
2. The `S3CFG` environment variable
3. `$HOME/.pegasus/s3cfg`
4. `$HOME/.s3cfg`

If it does not find the configuration file in one of these locations it will fail with an error. The `$HOME/.s3cfg` location is only supported for backward-compatibility. `$HOME/.pegasus/s3cfg` should be used instead.

Configuration File Format

The configuration file is in INI format and contains two types of entries.

The first type of entry is a site entry, which specifies the configuration for a storage service. This entry specifies the service endpoint that **pegasus-s3** should connect to for the site, and some optional features that the site may support. Here is an example of a site entry for Amazon S3:

```
[amazon]
endpoint = http://s3.amazonaws.com/
```

The other type of entry is an identity entry, which specifies the authentication information for a user at a particular site. Here is an example of an identity entry:

```
[pegasus@amazon]
access_key = 90c4143642cb097c88fe2ec66ce4ad4e
secret_key = a0e3840e5baee6abb08be68e81674dca
```

It is important to note that user names and site names used are only logical—they do not correspond to actual hostnames or usernames, but are simply used as a convenient way to refer to the services and identities used by the client.

The configuration file should be saved with limited permissions. Only the owner of the file should be able to read from it and write to it (i.e. it should have permissions of 0600 or 0400). If the file has more liberal permissions, then **pegasus-s3** will fail with an error message. The purpose of this is to prevent the authentication tokens stored in the configuration file from being accessed by other users.

Configuration Variables

endpoint (site)	The URL of the web service endpoint. If the URL begins with <i>https</i> , then SSL will be used.
max_object_size (site)	The maximum size of an object in GB (default: 5GB)
multipart_uploads (site)	Does the service support multipart uploads (True/False, default: False)
ranged_downloads (site)	Does the service support ranged downloads? (True/False, default: False)
access_key (identity)	The access key for the identity
secret_key (identity)	The secret key for the identity

Example Configuration

This is an example configuration that specifies a two sites (amazon and magellan) and three identities (pegasus@amazon, juve@magellan, and voeckler@magellan). For the amazon site the maximum object size is 5TB, and the site supports both multipart uploads and ranged downloads, so both uploads and downloads can be done in parallel.

```
[amazon]
endpoint = https://s3.amazonaws.com/
max_object_size = 5120
multipart_uploads = True
ranged_downloads = True

[pegasus@amazon]
access_key = 90c4143642cb097c88fe2ec66ce4ad4e
secret_key = a0e3840e5baee6abb08be68e81674dca

[magellan]
# NERSC Magellan is a Eucalyptus site. It doesn't support multipart uploads,
# or ranged downloads (the defaults), and the maximum object size is 5GB
# (also the default)
endpoint = https://128.55.69.235:8773/services/Walrus

[juve@magellan]
access_key = quwefahsdpflkewqjsdoijsdf
secret_key = asdfa9wejalsdjfljasldjfasdfa

[voeckler@magellan]
# Each site can have multiple associated identities
access_key = asdkfaweasdbaeiwhkjfbagwhei
secret_key = asdhfuinakwjelfuhalsdflahsdl
```

Example

List all buckets owned by identity *user@amazon*:

```
$ pegasus-s3 ls s3://user@amazon
```

List the contents of bucket *bar* for identity *user@amazon*:

```
$ pegasus-s3 ls s3://user@amazon/bar
```

List all objects in bucket *bar* that start with *hello*:

```
$ pegasus-s3 ls s3://user@amazon/bar/hello
```

Create a bucket called *mybucket* for identity *user@amazon*:

```
$ pegasus-s3 mkdir s3://user@amazon/mybucket
```

Delete a bucket called *mybucket*:

```
$ pegasus-s3 rmdir s3://user@amazon/mybucket
```

Upload a file *foo* to bucket *bar*:

```
$ pegasus-s3 putfoo s3://user@amazon/bar/foo
```

Download an object *foo* in bucket *bar*:

```
$ pegasus-s3 get s3://user@amazon/bar/foo foo
```

Upload a file in parallel with 4 threads and 100MB chunks:

```
$ pegasus-s3 put --parallel 4 --chunksize 100 foo s3://user@amazon/bar/foo
```

Download an object in parallel with 4 threads and 100MB chunks:

```
$ pegasus-s3 get --parallel 4 --chunksize 100 s3://user@amazon/bar/foo foo
```

List all partial uploads for bucket *bar*:

```
$ pegasus-s3 lsup s3://user@amazon/bar
```

Remove all partial uploads for bucket *bar*:

```
$ pegasus-s3 rmup --all s3://user@amazon/bar
```

Return Value

pegasus-s3 returns a zero exist status if the operation is successful. A non-zero exit status is returned in case of failure.

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-sc-client — generates a site catalog by querying sources.

Synopsis

```
pegasus-sc-client [-Dproperty=value...]  
                  [--source src]  
                  [-g|--grid grid]  
                  [-o|--vo vo]  
                  [-s|--sc scfile]  
                  [-p|--properties propfile]  
                  [-V|--version]  
                  [-v|--verbose]  
                  [-h|--help]
```

Description

pegasus-sc-client generates site catalog by querying sources like OSGMM, MYSOG, etc.

Options

-Dproperty=value	The -D option allows an experienced user to override certain properties which influence the program execution, among them the default location of the user's properties file and the PEGASUS_HOME location. One may set several CLI properties by giving this option multiple times.
--source src	The -D option(s) must be the first option on the command line. CLI properties take precedence over the file-based properties of the same key.
-g grid , --grid grid	the source to query for site information. Valid sources are: OSGMM
-o vo , --vo vo	the grid for which to generate the site catalog information.
-s scfile , --sc scfile	The Virtual Organization (VO) to which the user belongs. The default VO is LI-GO. The collector host should be set by default unless overridden by the property pegasus.catalog.site.osgmm.collector.host according to the following rules: <ul style="list-style-type: none">• if VO is ligo then collector host queried is ligo-osgmm.renci.org• if VO is engage then collector host queried is engage-central.renci.org• for any other VO, engage-central.renci.org will be queried and in all the paths the name of the engage VO will be replaced with the name of the VO passed. e.g if user specifies the VO to be cigi, engage will be replaced by cigi in the directory paths.
-p propfile , --properties propfile	The path to the created site catalog file
-v , --verbose	Generate a Pegasus properties file containing the SRM properties. The properties file is created only if --source is set to <i>OSGMM</i> .
-V , --version	Increases the verbosity of messages about what is going on.
-h , --help	Displays the current version of Pegasus.
	Displays all the options to the pegasus-sc-client command.

Example

Runs **pegasus-sc-client** and generates the site catalog:

```
$ pegasus-sc-client --source OSGMM --sc osg-sites.xml --vo LIGO --grid OSG
```

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-sc-converter — A client to convert site catalog from one format to another format.

Synopsis

```
pegasus-sc-converter [-v] [-V] [-h] [-Dproperty=value...]
                    [-I fmt] [-O fmt]
                    -i infile[,infile,...] -o outfile
```

Description

The **pegasus-sc-converter** program is used to convert the site catalog from one format to another.

Currently, the following formats of site catalog exist.

XML4 This format is a superset of previous formats. All information about a site that can be described about a site can be described in this format. In addition, the user has finer grained control over the specification of directories and FTP servers that are accessible at the **head node** and the **worker node**. The user can also specify which different file-servers for read/write operations

A sample entry in this format looks as follows

```
<site handle="osg" arch="x86" os="LINUX" osrelease="" osversion="" glibc="">
  <grid type="gt2" contact="viz-login.isi.edu/jobmanager-pbs" scheduler="PBS"
    jobtype="compute"/>
  <grid type="gt2" contact="viz-login.isi.edu/jobmanager-fork" scheduler="Fork"
    jobtype="auxillary"/>

  <directory path="/tmp" type="local-scratch">
    <file-server operation="put" url="file:///tmp"/>
  </directory>

  <profile namespace="pegasus" key="style">condor</profile>
  <profile namespace="condor" key="universe">vanilla</profile>
</site>
```

This format conforms to the XML schema found at <http://pegasus.isi.edu/schema/sc-4.0.xsd>.

XML3 This format is a superset of previous formats. All information about a site that can be described about a site can be described in this format. In addition, the user has finer grained control over the specification of directories and FTP servers that are accessible at the **head node** and the **worker node**.

A sample entry in this format looks as follows

```
<site handle="local" arch="x86" os="LINUX">
  <grid type="gt2" contact="viz-login.isi.edu/jobmanager-pbs" scheduler="PBS"
    jobtype="compute"/>
  <grid type="gt2" contact="viz-login.isi.edu/jobmanager-fork" scheduler="Fork"
    jobtype="auxillary"/>
  <head-fs>
    <scratch>
      <shared>
        <file-server protocol="gsiftp" url="gsiftp://viz-login.isi.edu" mount-point="/
scratch">
        </file-server>
        <internal-mount-point mount-point="/scratch" free-size="null" total-size="null"/>
      </shared>
    </scratch>
    <storage>
      <shared>
        <file-server protocol="gsiftp" url="gsiftp://viz-login.isi.edu" mount-point="/
scratch">
        </file-server>
        <internal-mount-point mount-point="/scratch" free-size="null" total-size="null"/>
      </shared>
    </storage>
  </head-fs>
  <replica-catalog type="LRC" url="rlsn://smarty.isi.edu">
  </replica-catalog>
```

```
<profile namespace="env" key="GLOBUS_LOCATION" >/nfs/software/globus/default</profile>
<profile namespace="env" key="LD_LIBRARY_PATH" >/nfs/software/globus/default/lib</
profile>
<profile namespace="env" key="PEGASUS_HOME" >/nfs/software/pegasus/default</profile>
</site>
```

This format conforms to the XML schema found at <http://pegasus.isi.edu/schema/sc-3.0.xsd>.

Options

- | | |
|---|---|
| -i <i>infile</i> [, <i>infile</i> ,...], --input <i>infile</i> [, <i>infile</i> ,...] | The comma separated list of input files that need to be converted to a file in the format specified by --oformat option. |
| -o <i>outfile</i> , --output <i>outfile</i> | The output file to which the output needs to be written out to. |

Other Options

- | | |
|--|--|
| -O <i>fmt</i> , --oformat <i>fmt</i> | The output format of the output file.
Valid values for the output format is XML3 , XML4 . |
| -v , --verbose | Increases the verbosity of messages about what is going on.
By default, all FATAL ERROR, ERROR , WARNINGS and INFO messages are logged. |
| -V , --version | Displays the current version number of the Pegasus Workflow Planner Software. |
| -h , --help | Displays all the options to the pegasus-plan command. |

Example

```
pegasus-sc-converter -i sites.xml -o sites.xml.new -O XML3 -vvvvv
```

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-statistics — A tool to generate statistics about the workflow run.

Synopsis

```
pegasus-statistics [-h|--help]
                  [-o|--output dir]
                  [-c|--conf propfile]
                  [-p|--statistics-level level]
                  [-t|--time-filter filter]
                  [-i|--ignore-db-inconsistency]
                  [-v|--verbose]
                  [-q|--quiet]
                  [-m|--multiple-wf]
                  [-p|--ispmc]
                  [-u|--isuuid]
                  [[submitdir ..] | [workflow_uuid ..]]
```

Description

pegasus-statistics generates statistics about the workflow run like total jobs/tasks/sub workflows ran, how many succeeded/failed etc. It generates job instance statistics like run time, condor queue delay etc. It generates invocation statistics information grouped by transformation name. It also generates job instance and invocation statistics information grouped by time and host.

Options

-h , --help	Prints a usage summary with all the available command-line options.
-o <i>dir</i> , --output <i>dir</i>	Writes the output to the given directory.
-c <i>propfile</i> , --conf <i>propfile</i>	The properties file to use. This option overrides all other property files.
-s <i>level</i> , --statistics-level <i>level</i>	<p>Specifies the statistics information to generate. Valid levels are: all, summary, wf_stats, jb_stats, tf_stats, and ti_stats. Default is summary. The output generated by pegasus-statistics is based on the the <i>level</i> set:</p> <ul style="list-style-type: none"> • all: generates all the statistics information. • summary: generates the workflow statistics summary. In the case of a hierarchical workflow the summary is across all sub workflows. • wf_stats: generates the workflow statistics information of each individual workflow. In case of a hierarchical workflow the workflow statistics are created for each sub workflow. • jb_stats: generates the job statistics information of each individual workflow. In case of hierarchical workflow the job statistics is created for each sub workflows. Note: Not supported when generating statistics over multiple workflows. • tf_stats: generates the invocation statistics information of each individual workflow grouped by transformation name .In case of hierarchical workflow the transformation statistics is created for each sub workflows. • ti_stats: generates the job instance and invocation statistics like total count and runtime grouped by time and host.
-t <i>filter</i> , --time-filter <i>filter</i>	<p>Specifies the time filter to group the time statistics. Valid <i>filter</i> values are: month, week, day, hour. Default is day.</p>

-i , --ignore-db-inconsistency	Turn off the the check for database consistency.
-v , --verbose	Increases the log level. If omitted, the default level will be set to WARNING. When this option is given, the log level is changed to INFO. If this option is repeated, the log level will be changed to DEBUG.
-q , --quiet	Decreases the log level. If omitted, the default level will be set to WARNING. When this option is given, the log level is changed to ERROR.
-m , --multiple-wf	Set this option when generating statistics over more than one workflow. The tool automatically sets this flag if multiple submit directories or multiple workflow UUIDs are provided. This option would need to be set explicitly only to generate statistics over all workflows in a single STAMPEDE database. NOTE: When workflows are specified as UUIDs the --conf options needs to be set for the tool to determine the STAMPEDE database URL.
-p , --ispmc	Set this flag to generate statistics for workflows which are run with PMC clustering enabled. It is recommended that this option be used when calculating statistics over multiple workflow runs.
-u , --isuuid	Set this option if the positional argument are workflow UUIDs. NOTE: When workflows are specified as UUIDs the --conf options needs to be set for the tool to determine the STAMPEDE database URL.

Example

Runs pegasus-statistics and writes the output to the given directory:

```
$ pegasus-statistics -o /scratch/statistics /scratch/grid-setup/run0001
```

Runs pegasus-statistics over a workflow run identified by a single workflow UUID:

```
$ pegasus-statistics --conf pegasusrc --isuuid 316f2986-7754-44ec-8b38-fcd0cb602ce0
```

Runs pegasus-statistics over a workflow run identified by a multiple workflow UUID:

```
$ pegasus-statistics --conf pegasusrc --isuuid 316f2986-7754-44ec-8b38-fcd0cb602ce0 \
7ef77af8-4eb2-45ca-b37d-c5a02186133a
```

Runs pegasus-statistics over all workflows in the STAMPEDE database:

```
$ pegasus-statistics --conf pegasusrc --multiple-wf
```

Authors

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-status — Pegasus workflow- and run-time status

Synopsis

```
pegasus-status [-h|--help]
               [-V|--version] [-v|--verbose] [-d|--debug]
               [-w|--watch [s]]
               [-L|--[no]legend] [-c|--[no]color] [-U|--[no]utf8]
               [-Q|--[no]queue] [-i|--[no]idle] [--[no]held]
               [--[no]heavy] [-S|--[no]success]
               [-j|--jobtype jt] [-s|--site sid]
               [-u|--user name]
               { [-l|--long] | [-r|--rows] }
               [rundir]
```

Description

pegasus-status shows the current state of the Condor Q and a workflow, depending on settings. If no valid run directory could be determined, including the current directory, **pegasus-status** will show all jobs of the current user and no workflows. If a run directory was specified, or the current directory is a valid run directory, status about the workflow will also be shown.

Many options will modify the behavior of this program, not withstanding a proper UTF-8 capable terminal, watch mode, the presence of jobs in the queue, progress in the workflow directory, etc.

Options

-h , --help	Prints a concise help and exits.
-V , --version	Prints the version information and exits.
-w [sec] , --watch [sec]	<p>This option enables the <i>watch mode</i>. In watch mode, the program repeatedly polls the status sources and shows them in an updating window. The optional argument <i>sec</i> to this option determines how often these sources are polled.</p> <p>We <i>strongly</i> recommend to set this interval not too low, as frequent polling will degrade the scheduler performance and increase the host load. In watch mode, the terminal size is the limiting factor, and parts of the output may be truncated to fit it onto the given terminal.</p> <p>Watch mode is disabled by default. The <i>sec</i> argument defaults to 60 seconds.</p>
-L , --legend , --nolegend	<p>This option shows a legend explaining the columns in the output, or turns off legends.</p> <p>By default, legends are turned off to save terminal real estate.</p>
-c , --color , --nocolor	<p>This option turns on (or off) ANSI color escape sequences in the output. The single letter option can only switch on colors.</p> <p>By default, colors are turned off, as they will not display well on a terminal with black background.</p>
-U , --utf8 , --noutf8	<p>This option turns on (or off) the output of Unicode box drawing characters as UTF-8 encoded sequences. The single option can only turn on box drawing characters.</p> <p>The defaults for this setting depend on the <i>LANG</i> environment variable. If the variable contains a value ending in something indicating UTF-8 capabilities, the option is turned on by default. It is off otherwise.</p>
-Q , --queue , --noqueue	This option turns on (or off) the output from parsing Condor Q.

	<p>By default, Condor Q will be parsed for jobs of the current user. If a workflow run directory is specified, it will furthermore be limited to jobs only belonging to the workflow.</p>
-v , --verbose	<p>This option increases the expert level, showing more information about the condor_q state. Being an incremental option, two increases are supported.</p> <p>Additionally, the signals <i>SIGUSR1</i> and <i>SIGUSR2</i> will increase and decrease the expert level respectively during run-time.</p> <p>By default, the simplest queue view is enabled.</p>
-d , --debug	<p>This is an internal debugging tool and should not be used outside the development team. As incremental option, it will show Pegasus-specific ClassAd tuples for each job, more in the second level.</p> <p>By default, debug mode is off.</p>
-u name , --user name	<p>This option permits to query the queue for a different user than the current one. This may be of interest, if you are debugging the workflow of another user.</p> <p>By default, the current user is assumed.</p>
-i , --idle , --noidle	<p>With this option, jobs in Condor state <i>idle</i> are omitted from the queue output.</p> <p>By default, <i>idle</i> jobs are shown.</p>
--held , --noheld	<p>This option enables or disabled showing of the reason a job entered Condor's <i>held</i> state. The reason will somewhat destroy the screen layout.</p> <p>By default, the reason is shown.</p>
--heavy , --noheavy	<p>If the terminal is UTF-8 capable, and output is to a terminal, this option decides whether to use heavyweight or lightweight line drawing characters.</p> <p>By default, heavy lines connect the jobs to workflows.</p>
-j jt , --jobtype jt	<p>This option filters the Condor jobs shown only to the Pegasus jobtypes given as argument or arguments to this option. It is a multi-option, and may be specified multiple times, and may use comma-separated lists. Use this option with an argument <i>help</i> to see all valid and recognized jobtypes.</p> <p>By default, all Pegasus jobtypes are shown.</p>
-s site , --site site	<p>This option limits the Condor jobs shown to only those pertaining to the (remote) site <i>site</i>. This is a multi-option, and may be specified multiple times, and may use comma-separated lists.</p> <p>By default, all sites are shown.</p>
-l , --long	<p>This option will show one line per sub-DAG, including one line for the workflow. If there is only a single DAG pertaining to the <i>rundir</i>, only total will be shown.</p> <p>This option is mutually exclusive with the --rows option. If both are specified, the --long option takes precedence.</p> <p>By default, only DAG totals (sums) are shown.</p>
-r , --rows , --norows	<p>This option is shows the workflow summary statistics in rows instead of columns. This option is useful for sending the statistics in email and later viewing them in a proportional font.</p> <p>This option is mutually exclusive with the --long option. If both are specified, the --long option takes precedence.</p>

By default, the summary is shown in columns.

-S , --success , --no-success This option modifies the previous **--long** option. It will omit (or show) fully successful sub-DAGs from the output.

By default, all DAGs are shown.

rundir This option show statistics about the given DAG that runs in *rundir*. To gather proper statistics, **pegasus-status** needs to traverse the directory and all sub-directories. This can become an expensive operation on shared filesystems.

By default, the *rundir* is assumed to be the current directory. If the current directory is not a valid *rundir*, no DAG statistics will be shown.

Return Value

pegasus-status will typically return success in regular mode, and the termination signal in watch mode. Abnormal behavior will result in a non-zero exit code.

Example

pegasus-status This invocation will parse the Condor Q for the current user and show all her jobs. Additionally, if the current directory is a valid Pegasus workflow directory, totals about the DAG in that directory are displayed.

pegasus-status -l rundir As above, but providing a specific Pegasus workflow directory in argument *rundir* and requesting to itemize sub-DAGs.

pegasus-status -j help This option will show all permissible job types and exit.

pegasus-status -vvw 300 -LI This invocation will parse the queue, print it in high-expert mode, show legends, itemize DAG statistics of the current working directory, and redraw the terminal every five minutes with updated statistics.

Restrictions

Currently only supports a single (optional) run directory. If you want to watch multiple run directories, I suggest to open multiple terminals and watch them separately. If that is not an option, or deemed too expensive, you can ask *pegasus-support at isi dot edu* to extend the program.

Name

pegasus-submit-dag — Wrapper around `*condor_submit_dag*`. Not to be run by user.

Description

The **pegasus-submit-dag** is a wrapper that invokes **condor_submit_dag**. This is started automatically by **pegasus-run**. **DO NOT USE DIRECTLY**

Return Value

If the workflow is submitted successfully **pegasus-submit-dag** exits with 0, else exits with non-zero.

Environment Variables

PATH The path variable is used to locate binary for **condor_submit_dag** and **pegasus-dagman**

Pegasus Team <http://pegasus.isi.edu>

Name

`pegasus-tc-client` — A full featured generic client to handle adds, deletes and queries to the Transformation Catalog (TC).

Synopsis

```
pegasus-tc-client [-Dproperty=value...] [-h] [-v] [-V]  
OPERATION TRIGGERS [OPTIONS]
```

Description

The **pegasus-tc-client** command is a generic client that performs the three basic operation of adding, deleting and querying of any Transformation Catalog implemented to the TC API. The client implements all the operations supported by the TC API. It is up to the TC implementation whether they support all operations or modes.

The following 3 operations are supported by the **pegasus-tc-client**. One of these operations have to be specified to run the client.

- | | |
|---------------|---|
| ADD | This operation allows the client to add or update entries in the Transformation Catalog. Entries can be added one by one on the command line or in bulk by using the <i>BULK</i> Trigger and providing a file with the necessary entries. Also Profiles can be added to either the logical transformation or the physical transformation. |
| DELETE | This operation allows the client to delete entries from the Transformation Catalog. Entries can be deleted based on logical transformation, by resource, by transformation type as well as the transformation system information. Also Profiles associated with the logical or physical transformation can be deleted. |
| QUERY | This operation allows the client to query for entries from the Transformation Catalog. Queries can be made for printing all the contents of the Catalog or for specific entries, for all the logical transformations or resources etc. |

See the **TRIGGERS** and **VALID COMBINATIONS** section for more details.

Operations

To select one of the 3 operations.

- | | |
|---------------------|--|
| -a, --add | Perform addition operations on the TC. |
| -d, --delete | Perform delete operations on the TC. |
| -q, --query | Perform query operations on the TC. |

Triggers

Triggers modify the behavior of an **OPERATION**. For example, if you want to perform a bulk operation you would use a *BULK* Trigger or if you want to perform an operation on a Logical Transformation then you would use the *LFN* Trigger.

The following 7 Triggers are available. See the **VALID COMBINATIONS** section for the correct grouping and usage.

- | | |
|-----------|--|
| -B | Triggers a bulk operation. |
| -L | Triggers an operation on a logical transformation. |
| -P | Triggers an operation on a physical transformation |
| -R | Triggers an operation on a resource. |
| -E | Triggers an operation on a Profile. |
| -T | Triggers an operation on a Type. |

-S Triggers an operation on a System information.

Options

The following options are applicable for all the operations.

-D <i>property=value</i>	The -D options allows an experienced user to override certain properties which influence the program execution, among them the default location of the user's properties file and the PEGASUS home location. One may set several CLI properties by giving this option multiple times. The -D option(s) must be the first option on the command line. A CLI property take precedence over the properties file property of the same key.
-l, --lfn <i>logical</i>	The logical transformation to be added. The format is: NAMESPACE::NAME:VERSION . The name is always required, namespace and version are optional.
-p, --pfn <i>physical</i>	The physical transformation to be added. For INSTALLED executables its a local file path, for all others its a url.
-t, --type <i>type</i>	The type of physical transformation. Valid values are: INSTALLED, STATIC_BINARY, DYNAMIC_BINARY, SCRIPT, SOURCE, PACMAN_PACKAGE.
-r, --resource <i>resource</i>	The resourceID where the transformation is located.
-e, --profile <i>profiles</i>	The profiles for the transformation. Multiple profiles of same namespace can be added simultaneously by separating them with a comma ",". Each profile section is written as NAMESPACE::KEY=VALUE,KEY2=VALUE2 e.g. ENV::JAVA_HOME=/usr/bin/java2,PEGASUS_HOME=/usr/local/pegasus. To add multiple namespaces you need to repeat the -e option for each namespace. e.g. -e ENV::JAVA_HOME=/usr/bin/java -e GLOBUS::JobType=MPI,COUNT=10
-s, --system <i>systeminfo</i>	The architecture, os, osversion and glibc if any for the executable. Each system info is written in the form ARCH::OS:OSVER:GLIBC
-v, --verbose	Displays the output in verbose mode (Lots of Debugging info).
-V, --version	Displays the Pegasus version.
-h, --help	Generates help

Other Options

-o, --oldformat	Generates the output in the old single line format
-c, --conf	path to property file

Valid Combinations

The following are valid combinations of **OPERATIONS**, **TRIGGERS**, **OPTIONS** for the **pegasus-tc-client**.

ADD

Add TC Entry	-a -l lfn -p pfn -t type -r resource -s system [-e profiles...] Adds a single entry into the transformation catalog.
Add PFN Profile	-a -P -E -p pfn -t type -r resource -e profiles ... Adds profiles to a specified physical transformation on a given resource and of a given type.

Add LFN Profile

`-a -L -E -l lfn -e profiles ...`

Adds profiles to a specified logical transformation.

Add Bulk Entries

`-a -B -f file`

Adds entries in bulk mode by supplying a file containing the entries. The format of the file contains 6 columns. E.g.

```
#RESOURCE    LFN                PFN                TYPE                SYSINFO                PROFILES
#
isi NS::NAME:VER /bin/date  INSTALLED  ARCH::OS:OSVERS:GLIBC
NS::KEY=VALUE,KEY=VALUE;NS2::KEY=VALUE,KEY=VALUE
```

DELETE**Delete all TC**

`-d -BPRELST`

Deletes the entire contents of the TC.

WARNING : USE WITH CAUTION.

Delete by LFN

`-d -L -l lfn [-r resource] [-t type]`

Deletes entries from the TC for a particular logical transformation and additionally a resource and or type.

Delete by PFN

`-d -P -l lfn -p pfm [-r resource] [-t type]`

Deletes entries from the TC for a given logical and physical transformation and additionally on a particular resource and or of a particular type.

Delete by Type

`-d -T -t type [-r resource]`

Deletes entries from TC of a specific type and/or on a specific resource.

Delete by Resource

`-d -R -r resource`

Deletes the entries from the TC on a particular resource.

Delete by SysInfo

`-d -S -s sysinfo`

Deletes the entries from the TC for a particular system information type.

Delete Pfn Profile

`-d -P -E -p pfm -r resource -t type [-e profiles ..]`

Deletes all or specific profiles associated with a physical transformation.

Delete Lfn Profile

`-d -L -E -l lfn -e profiles`

Deletes all or specific profiles associated with a logical transformation.

QUERY**Query Bulk**

`-q -B`

Queries for all the contents of the TC. It produces a file format TC which can be added to another TC using the bulk option.

Query LFN

`-q -L [-r resource] [-t type]`

Queries the TC for logical transformation and/or on a particular resource and/or of a particular type.

Query PFN

`-q -P -l lfn [-r resource] [-t type]`

	Queries the TC for physical transformations for a give logical transformation and/or on a particular resource and/or of a particular type.
Query Resource	<code>-q -R -l lfn [-t type]</code>
	Queries the TC for resources that are registered and/or resources registered for a specific type of transformation.
Query LFN Profile	<code>-q -L -E -l lfn</code>
	Queries for profiles associated with a particular logical transformation
Query Pfn Profile	<code>-q -P -E -p pfn -r resource -t type</code>
	Queries for profiles associated with a particular physical transformation

Properties

These are the properties you will need to set to use either the **File** or **Database** TC.

For more details please check the `$PEGASUS_HOME/etc/sample.properties` file.

pegasus.catalog.transformation	Identifies what implemtnation of TC will be used. If relative name is used then the path <code>org.griphyn.cPlanner.tc</code> is prefixed to the name and used as the class name to load. The default value if Text . Other supported mode is File
pegasus.catalog.transformation.file	The file path where the text based TC is located. By default the path <code>\$PEGASUS_HOME/var/tc.data</code> is used.

Files

\$PEGASUS_HOME/var/tc.data	is the suggested location for the file corresponding to the Transformation Catalog
\$PEGASUS_HOME/etc/properties	is the location to specify properties to change what Transformation Catalog Implementation to use and the implementation related PROPERTIES .
pegasus.jar	contains all compiled Java bytecode to run the Pegasus planner.

Environment Variables

PEGASUS_HOME	Path to the PEGASUS installation directory.
JAVA_HOME	Path to the JAVA 1.4.x installation directory.
CLASSPATH	The classpath should be set to contain all necessary PEGASUS files for the execution environment. To automatically add the <i>CLASSPATH</i> to you environment, in the <i>\$PEGASUS_HOME</i> directory run the script <i>source setup-user-env.csh</i> or <i>source setup-user-env.sh</i> .

Karan Vahi <vahi at isi dot edu>

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-tc-converter — A client to convert transformation catalog from one format to another format.

Synopsis

```
pegasus-tc-converter [-Dproperty=value...] [-v] [-q] [-V] [-h]
                    [-I fmt] [-O fmt]
                    [-N dbusername] [-P dbpassword] [-U dburl] [-H dbhost]
                    -i infile[,infile,...] -o outfile
```

Description

The tc-convert program is used to convert the transformation catalog from one format to another.

Currently, the following formats of transformation catalog exist:

Text This is a easy to read multi line textual format.

A sample entry in this format looks as follows:

```
tr example::keg:1.0 {
    site isi {
        profile env "JAVA_HOME" "/bin/java.1.6"
        pfn "/path/to/keg"
        arch "x86"
        os "linux"
        osrelease "fc"
        osversion "4"
        type "installed"
    }
}
```

File This is a tuple based format which contains 6 columns.

```
RESOURCE  LFN  PFN  TYPE  SYSINFO  PROFILES
```

A sample entry in this format looks as follows

```
isi example::keg:1.0 /path/to/keg  INSTALLED  INTEL32::LINUX:fc_4:
env::JAVA_HOME="/bin/java.1.6"
```

Database Only MySQL is supported for the time being.

Options

-Dproperty=value The **-D** option allows an experienced user to override certain properties which influence the program execution, among them the default location of the user's properties file and the **PEGASUS_HOME** location. One may set several CLI properties by giving this option multiple times.

The **-D** option(s) must be the first option on the command line. CLI properties take precedence over the file-based properties of the same key.

-I *fmt* , --iformat *fmt* The input format of the input files. Valid values for the input format are: **File**, **Text**, and **Database**.

-O *fmt* --oformat *fmt* The output format of the output file. Valid values for the output format are: **File**, **Text**, and **Database**.

-i *infile*[,*infile*,...] --input *infile*[,*infile*,...] The comma separated list of input files that need to be converted to a file in the format specified by the **--oformat** option.

-o *outfile* , --output *outfile* The output file to which the output needs to be written out to.

Other Options

-N <i>dbusername</i> , --db-user-name <i>dbusername</i>	The database user name.
-P <i>dbpassword</i> , --db-user-pwd <i>dbpassword</i>	The database user password.
-U <i>dburl</i> , --db-url <i>dburl</i>	The database url.
-H <i>dbhost</i> , --db-host <i>dbhost</i>	The database host.
-v , --verbose	Increases the verbosity of messages about what is going on. By default, all FATAL ERROR, ERROR , CONSOLE and WARNINGS messages are logged.
-q , --quiet	Decreases the verbosity of messages about what is going on. By default, all FATAL ERROR, ERROR , CONSOLE and WARNINGS messages are logged.
-V , --version	Displays the current version number of the Pegasus Workflow Planner Software.
-h , --help	Displays all the options to the pegasus-tc-converter command.

Example

Text to file format conversion

```
pegasus-tc-converter -i tc.data -I File -o tc.txt -O Text -v
```

File to Database(new) format conversion

```
pegasus-tc-converter -i tc.data -I File -N mysql_user -P mysql_pwd -U jdbc:mysql://localhost:3306/tc  
-H localhost -O Database -v
```

Database (username, password,
host, url specified in properties file)
to text format conversion

```
pegasus-tc-converter -I Database -o tc.txt -O Text -vvvvv
```

Authors

Prasanth Thomas

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-transfer — Handles data transfers in Pegasus workflows.

Synopsis

```
pegasus-transfer [-h]
                  [-l level] [-f inputfile]
                  [--max-attempts attempts]
```

Description

pegasus-transfer takes a list of url pairs, either on stdin or with an input file, determines the correct tool to use for the transfer and executes the transfer. Some of the protocols pegasus-transfer can handle are GridFTP, SRM, Amazon S3, HTTP, and local cp/symlinking. Failed transfers are retried.

Options

-h , --help	Prints a usage summary with all the available command-line options.
-l <i>level</i> , --loglevel <i>level</i>	The debugging output level. Valid values are: debug , info , warning , error . Default value is info .
-f <i>inputfile</i> , --file <i>inputfile</i>	File with input pairs. If not given, stdin will be used.
--max-attempts <i>attempts</i>	Maximum number of attempts for retrying failed transfers.

Example

```
$ pegasus-transfer
file:///etc/hosts
file:///tmp/foo
CTRL+D
```

Author

Pegasus Team <http://pegasus.isi.edu>

Name

pegasus-version — print or match the version of the toolkit.

Synopsis

pegasus-version [-D*property=value*] [-m [-q]] [-V] [-f] [-l]

Description

This program prints the version string of the currently active Pegasus toolkit on *stdout*.

pegasus-version is a simple command-line tool that reports the version number of the Pegasus distribution being used. In its most basic invocation, it will show the current version of the Pegasus software you have installed:

```
$ pegasus-version
3.1.0cvs
```

If you want to know more details about the installed version, i.e. which system it was compiled for and when, use the long or full mode:

```
$ pegasus-version -f
3.1.0cvs-x86_64-cent_5.6-20110706191019Z
```

Options

-D <i>property=value</i>	The -D option allows an experienced user to override certain properties which influence the program execution, among them the default location of the user's properties file and the PEGASUS_HOME location. One may set several CLI properties by giving this option multiple times.
	The -D option(s) must be the first option on the command line. CLI properties take precedence over the file-based properties of the same key.
-f , --full	The --full mode displays internal build metrics, like OS type and libc version, addition to the version number. It appends the build time as time stamp to the version. The time stamp uses ISO 8601 format, and is a UTC stamp.
-l , --long	This option is an alias for --full .
-V , --version	Displays the version of the Pegasus planner you are using.
--verbose	is ignored in this tool. However, to provide a uniform interface for all tools, the option is recognized and will not trigger an error.

Return Value

The program will usually return with success (0). In match mode, if the internal version does not match the external installation, an exit code of 1 is returned. If run-time errors are detected, an exit code of 2 is returned, 3 for fatal errors.

Environment Variables

JAVA_HOME should be set and point to a valid location to start the intended Java virtual machine as *\$JAVA_HOME/bin/java*.

Example

```
$ pegasus-version
3.1.0cvs

$ pegasus-version -f
3.1.0cvs-x86_64-cent_5.6-20110706191019Z
```

Jens-S. Vöckler <voeckler at isi dot edu>

Pegasus Team <http://pegasus.isi.edu>

Chapter 11. Useful Tips

Migrating From Pegasus 3.1 to Pegasus 4.X

With Pegasus 4.0 effort has been made to move the Pegasus installation to be FHS compliant, and to make workflows run better in Cloud environments and distributed grid environments. This chapter is for existing users of Pegasus who use Pegasus 3.1 to run their workflows and walks through the steps to move to using Pegasus 4.0

Move to FHS layout

Pegasus 4.0 is the first release of Pegasus which is Filesystem Hierarchy Standard (FHS) [<http://www.pathname.com/fhs/>] compliant. The native packages no longer installs under /opt. Instead, pegasus-* binaries are in /usr/bin/ and example workflows can be found under /usr/share/pegasus/examples/.

To find Pegasus system components, a pegasus-config tool is provided. pegasus-config supports setting up the environment for

- Python
- Perl
- Java
- Shell

For example, to find the PYTHONPATH for the DAX API, run:

```
export PYTHONPATH=`pegasus-config --python`
```

For complete description of pegasus-config, see the man page.

Stampede Schema Upgrade Tool

Starting Pegasus 4.x the monitoring and statistics database schema has changed. If you want to use the pegasus-statistics, pegasus-analyzer and pegasus-plots against a 3.x database you will need to upgrade the schema first using the schema upgrade tool /usr/share/pegasus/sql/schema_tool.py or /path/to/pegasus-4.x/share/pegasus/sql/schema_tool.py

Upgrading the schema is required for people using the MySQL database for storing their monitoring information if it was setup with 3.x monitoring tools.

If your setup uses the default SQLite database then the new databases run with Pegasus 4.x are automatically created with the correct schema. In this case you only need to upgrade the SQLite database from older runs if you wish to query them with the newer clients.

To upgrade the database

For SQLite Database

```
cd /to/the/workflow/directory/with/3.x.monitordb
```

Check the db version

```
/usr/share/pegasus/sql/schema_tool.py -c connString=sqlite:///to/the/workflow/directory/with/
workflow.stampede.db
2012-02-29T01:29:43.330476Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.init |
2012-02-29T01:29:43.330708Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema.start |
2012-02-29T01:29:43.348995Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema
| Current version set to: 3.1.
2012-02-29T01:29:43.349133Z ERROR netlogger.analysis.schema.schema_check.SchemaCheck.check_schema
```

```
| Schema version 3.1 found - expecting 4.0 - database admin will
need to run upgrade tool.
```

Convert the Database to be version 4.x compliant

```
/usr/share/pegasus/sql/schema_tool.py -u connString=sqlite:///to/the/workflow/directory/with/
workflow.stamped.db
2012-02-29T01:35:35.046317Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.init |
2012-02-29T01:35:35.046554Z INFO
netlogger.analysis.schema.schema_check.SchemaCheck.check_schema.start |
2012-02-29T01:35:35.064762Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema
| Current version set to: 3.1.
2012-02-29T01:35:35.064902Z ERROR netlogger.analysis.schema.schema_check.SchemaCheck.check_schema
| Schema version 3.1 found - expecting 4.0 - database admin will
need to run upgrade tool.
2012-02-29T01:35:35.065001Z INFO
netlogger.analysis.schema.schema_check.SchemaCheck.upgrade_to_4_0
| Upgrading to schema version 4.0.
```

Verify if the database has been converted to Version 4.x

```
/usr/share/pegasus/sql/schema_tool.py -c connString=sqlite:///to/the/workflow/directory/with/
workflow.stamped.db
2012-02-29T01:39:17.218902Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.init |
2012-02-29T01:39:17.219141Z INFO
netlogger.analysis.schema.schema_check.SchemaCheck.check_schema.start |
2012-02-29T01:39:17.237492Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema |
Current version set to: 4.0.
2012-02-29T01:39:17.237624Z INFO netlogger.analysis.schema.schema_check.SchemaCheck.check_schema |
Schema up to date.
```

For upgrading a MySQL database the steps remain the same. The only thing that changes is the connection String to the database
E.g.

```
/usr/share/pegasus/sql/schema_tool.py -u connString=mysql://username:password@server:port/dbname
```

After the database has been upgraded you can use either 3.x or 4.x clients to query the database with **pegasus-statistics**, as well as **pegasus-plots** and **pegasus-analyzer**.

Existing users running in a condor pool with a non shared filesystem setup

Existing users that are running workflows in a cloud environment with a non shared filesystem setup have to do some trickery in the site catalog to include placeholders for local/submit host paths for execution sites when using CondorIO. In Pegasus 4.0, this has been rectified.

For example, for a 3.1 user, to run on a local-condor pool without a shared filesystem and use Condor file IO for file transfers, the site entry looks something like this

```
<site handle="local-condor" arch="x86" os="LINUX">
  <grid type="gt2" contact="localhost/jobmanager-fork" scheduler="Fork" jobtype="auxillary"/>
  <grid type="gt2" contact="localhost/jobmanager-condor" scheduler="unknown"
jobtype="compute"/>
  <head-fs>

  <!-- the paths for scratch filesystem are the paths on local site as we execute create dir
job
on local site. Improvements planned for 4.0 release.-->
  <scratch>
    <shared>
      <file-server protocol="file" url="file://" mount-point="/submit-host/scratch"/>
      <internal-mount-point mount-point="/submit-host/scratch"/>
    </shared>
  </scratch>
  <storage>
    <shared>
      <file-server protocol="file" url="file://" mount-point="/glusterfs/scratch"/>
      <internal-mount-point mount-point="/glusterfs/scratch"/>
    </shared>
  </storage>
```

```

</head-fs>
<replica-catalog type="LRC" url="rlsn://dummyValue.url.edu" />
<profile namespace="env" key="PEGASUS_HOME" >/cluster-software/pegasus/2.4.1</profile>
<profile namespace="env" key="GLOBUS_LOCATION" >/cluster-software/globus/5.0.1</profile>

<!-- profiles for site to be treated as condor pool -->
<profile namespace="pegasus" key="style" >condor</profile>
<profile namespace="condor" key="universe" >vanilla</profile>

<!-- to enable kickstart staging from local site-->
<profile namespace="condor" key="transfer_executable">true</profile>

</site>

```

With Pegasus 4.0 the site entry for a local-condor pool can be as concise as the following

```

<site handle="condorpool" arch="x86" os="LINUX">
  <head-fs>
    <scratch />
    <storage />
  </head-fs>
  <profile namespace="pegasus" key="style" >condor</profile>
  <profile namespace="condor" key="universe" >vanilla</profile>
</site>

```

The planner in 4.0 correctly picks up the paths from the local site entry to determine the staging location for the condor io on the submit host.

Users should read pegasus data staging configuration chapter and also look in the examples directory (share/pegasus/examples).

New Clients for directory creation and file cleanup

Pegasus 4.0 has new clients for directory creation and cleanup.

- pegasus-create-dir
- pegasus-cleanup

Both these clients are python based wrapper scripts around various protocol specific clients that are used to determine what client to pick up.

Table 11.1. Clients interfaced to by pegasus-create-dir

Client	Used For
globus-url-copy	to create directories against a gridftp/ftp server
srm-mkdir	to create directories against a SRM server.
mkdir	to create a directory on the local filesystem
pegasus-s3	to create a s3 bucket in the amazon cloud
scp	staging files using scp
imkdir	to create a directory against an IRODS server

Table 11.2. Clients interfaced to by pegasus-cleanup

Client	Used For
globus-url-copy	to remove a file against a gridftp/ftp server. In this case a zero byte file is created
srm-rm	to remove files against a SRM server.
rm	to remove a file on the local filesystem

Client	Used For
pegasus-s3	to remove a file from the s3 bucket.
scp	to remove a file against a scp server. In this case a zero byte file is created.
irm	to remove a file against an IRODS server

With Pegasus 4.0, the planner will prefer to run the create dir and cleanup jobs locally on the submit host. The only case, where these jobs are scheduled to run remotely is when for the staging site, a file server is specified.

Migrating From Pegasus 2.X to Pegasus 3.X

With Pegasus 3.0 effort has been made to simplify configuration. This chapter is for existing users of Pegasus who use Pegasus 2.x to run their workflows and walks through the steps to move to using Pegasus 3.0

PEGASUS_HOME and Setup Scripts

Earlier versions of Pegasus required users to have the environment variable PEGASUS_HOME set and to source a setup file \$PEGASUS_HOME/setup.sh | \$PEGASUS_HOME/setup.csh before running Pegasus to setup CLASSPATH and other variables.

Starting with Pegasus 3.0 this is no longer required. The above paths are automatically determined by the Pegasus tools when they are invoked.

All the users need to do is to set the PATH variable to pick up the pegasus executables from the bin directory.

```
$ export PATH=/some/install/pegasus-3.0.0/bin:$PATH
```

Changes to Schemas and Catalog Formats

DAX Schema

Pegasus 3.0 by default now parses DAX documents conforming to the DAX Schema 3.2 available here [<http://pegasus.isi.edu/wms/docs/schemas/dax-3.2/dax-3.2.xsd>] and is explained in detail in the chapter on API references.

Starting Pegasus 3.0 , DAX generation API's are provided in Java/Python and Perl for users to use in their DAX Generators. The use of API's is highly encouraged. Support for the old DAX schema's has been deprecated and will be removed in a future version.

For users, who still want to run using the old DAX formats i.e 3.0 or earlier, can for the time being set the following property in the properties and point it to dax-3.0 xsd of the installation.

```
pegasus.schema.dax /some/install/pegasus-3.0/etc/dax-3.0.xsd
```

Site Catalog Format

Pegasus 3.0 by default now parses Site Catalog format conforming to the SC schema 3.0 (XML3) available here [<http://pegasus.isi.edu/wms/docs/schemas/dax-3.2/dax-3.2.xsd>] and is explained in detail in the chapter on Catalogs.

Pegasus 3.0 comes with a pegasus-sc-converter that will convert users old site catalog (XML) to the XML3 format. Sample usage is given below.

```
$ pegasus-sc-converter -i sample.sites.xml -I XML -o sample.sites.xml3 -O XML3
```

```
2010.11.22 12:55:14.169 PST:   Written out the converted file to sample.sites.xml3
```

To use the converted site catalog, in the properties do the following

1. unset pegasus.catalog.site or set pegasus.catalog.site to XML3
2. point pegasus.catalog.site.file to the converted site catalog

Transformation Catalog Format

Pegasus 3.0 by default now parses a file based multiline textual format of a Transformation Catalog. The new Text format is explained in detail in the chapter on Catalogs.

Pegasus 3.0 comes with a `pegasus-tc-converter` that will convert users old transformation catalog (File) to the Text format. Sample usage is given below.

```
$ pegasus-tc-converter -i sample.tc.data -I File -o sample.tc.text -O Text

2010.11.22 12:53:16.661 PST:   Successfully converted Transformation Catalog from File to Text
2010.11.22 12:53:16.666 PST:   The output transformation catalog is in file  /lfs1/software/install/
pegasus/pegasus-3.0.0cvs/etc/sample.tc.text
```

To use the converted transformation catalog, in the properties do the following

1. unset `pegasus.catalog.transformation` or set `pegasus.catalog.transformation` to Text
2. point `pegasus.catalog.transformation.file` to the converted transformation catalog

Properties and Profiles Simplification

Starting with Pegasus 3.0 all profiles can be specified in the properties file. Profiles specified in the properties file have the lowest priority. Profiles are explained in the detail in the Profiles chapter. As a result of this a lot of existing Pegasus Properties were replaced by profiles. The table below lists the properties removed and the new profile based names.

Table 11.3. Table 1: Property Keys removed and their Profile based replacement

Old Property Key	New Property Key
<code>pegasus.local.env</code>	no replacement. Specify env profiles for local site in the site catalog
<code>pegasus.condor.release</code>	<code>condor.periodic_release</code>
<code>pegasus.condor.remove</code>	<code>condor.periodic_remove</code>
<code>pegasus.job.priority</code>	<code>condor.priority</code>
<code>pegasus.condor.output.stream</code>	<code>pegasus.condor.output.stream</code>
<code>pegasus.condor.error.stream</code>	<code>condor.stream_error</code>
<code>pegasus.dagman.retry</code>	<code>dagman.retry</code>
<code>pegasus.exitcode.impl</code>	<code>dagman.post</code>
<code>pegasus.exitcode.scope</code>	<code>dagman.post.scope</code>
<code>pegasus.exitcode.arguments</code>	<code>dagman.post.arguments</code>
<code>pegasus.exitcode.path.*</code>	<code>dagman.post.path.*</code>
<code>pegasus.dagman.maxpre</code>	<code>dagman.maxpre</code>
<code>pegasus.dagman.maxpost</code>	<code>dagman.maxpost</code>
<code>pegasus.dagman.maxidle</code>	<code>dagman.maxidle</code>
<code>pegasus.dagman.maxjobs</code>	<code>dagman.maxjobs</code>
<code>pegasus.remote.scheduler.min.maxwalltime</code>	<code>globus.maxwalltime</code>
<code>pegasus.remote.scheduler.min.maxtime</code>	<code>globus.maxtime</code>
<code>pegasus.remote.scheduler.min.maxcputime</code>	<code>globus.maxcputime</code>
<code>pegasus.remote.scheduler.queues</code>	<code>globus.queue</code>

Profile Keys for Clustering

The pegasus profile keys for job clustering were **renamed**. The following table lists the old and the new names for the profile keys.

Table 11.4. Table 2: Old and New Names For Job Clustering Profile Keys

Old Pegasus Profile Key	New Pegasus Profile Key
collapse	clusters.size
bundle	clusters.num

Transfers Simplification

Pegasus 3.0 has a new default transfer client `pegasus-transfer` that is invoked by default for first level and second level staging. The `pegasus-transfer` client is a python based wrapper around various transfer clients like `globus-url-copy`, `lcg-copy`, `wget`, `cp`, `ln`. `pegasus-transfer` looks at source and destination url and figures out automatically which underlying client to use. `pegasus-transfer` is distributed with the PEGASUS and can be found in the `bin` subdirectory.

Also, the Bundle Transfer refiner has been made the default for pegasus 3.0. Most of the users no longer need to set any transfer related properties. The names of the profiles keys that control the Bundle Transfers have been changed. The following table lists the old and the new names for the Pegasus Profile Keys and are explained in details in the Profiles Chapter.

Table 11.5. Table 3: Old and New Names For Transfer Bundling Profile Keys

Old Pegasus Profile Key	New Pegasus Profile Keys
bundle.stagein	stagein.clusters stagein.local.clusters stagein.remote.clusters
bundle.stageout	stageout.clusters stageout.local.clusters stageout.remote.clusters

Worker Package Staging

Starting Pegasus 3.0 there is a separate boolean property **`pegasus.transfer.worker.package`** to enable worker package staging to the remote compute sites. Earlier it was bundled with user executables staging i.e if **`pegasus.catalog.transformation.mapper`** property was set to Staged.

Clients in bin directory

Starting with Pegasus 3.0 the pegasus clients in the `bin` directory have a pegasus prefix. The table below lists the old client names and new names for the clients that replaced them

Table 11.6. Table 1: Old Client Names and their New Names

Old Client	New Client
rc-client	pegasus-rc-client
tc-client	pegasus-tc-client
pegasus-get-sites	pegasus-sc-client
sc-client	pegasus-sc-converter
tailstatd	pegasus-monitor
genstats and genstats-breakdown	pegasus-statistics
show-job	pegasus-plots
cleanup	pegasus-cleanup
dirmanager	pegasus-dirmanager
exitcode	pegasus-exitcode
rank-dax	pegasus-rank-dax
transfer	pegasus-transfer

Best Practices For Developing Portable Code

This document lists out issues for the algorithm developers to keep in mind while developing the respective codes. Keeping these in mind will alleviate a lot of problems while trying to run the codes on the Grid through workflows.

Supported Platforms

Most of the hosts making a Grid run variants of Linux or in some case Solaris. The Grid middleware mostly supports UNIX and its variants.

Running on Windows

The majority of the machines making up the various Grid sites run Linux. In fact, there is no widespread deployment of a Windows-based Grid. Currently, the server side software of Globus does not run on Windows. Only the client tools can run on Windows. The algorithm developers should not code exclusively for the Windows platforms. They must make sure that their codes run on Linux or Solaris platforms. If the code is written in a portable language like Java, then porting should not be an issue.

If for some reason the code can only be executed on windows platform, please contact the pegasus team at pegasus at isi dot edu . In certain cases it is possible to stand up a linux headnode in front of a windows cluster running Condor as its scheduler.

Packaging of Software

As far as possible, binary packages (preferably statically linked) of the codes should be provided. If for some reason the codes, need to be built from the source then they should have an associated makefile (for C/C++ based tools) or an ant file (for Java tools). The building process should refer to the standard libraries that are part of a normal Linux installation. If the codes require non-standard libraries, clear documentation needs to be provided, as to how to install those libraries, and make the build process refer to those libraries.

Further, installing software as root is not a possibility. Hence, all the external libraries that need to be installed can only be installed as non-root in non-standard locations.

MPI Codes

If any of the algorithm codes are MPI based, they should contact the Grid group. MPI can be run on the Grid but the codes need to be compiled against the installed MPI libraries on the various Grid sites. The pegasus group has some experience running MPI code through PBS.

Maximum Running Time of Codes

Each of the Grid sites has a policy on the maximum time for which they will allow a job to run. The algorithms catalog should have the maximum time (in minutes) that the job can run for. This information is passed to the Grid sites while submitting a job, so that Grid site does not kill a job before that published time expires. It is OK, if the job runs only a fraction of the max time.

Codes cannot specify the directory in which they should be run

Codes are installed in some standard location on the Grid Sites or staged on demand. However, they are not invoked from directories where they are installed. The codes should be able to be invoked from any directory, as long as one can access the directory where the codes are installed.

This is especially relevant, while writing scripts around the algorithm codes. At that point specifying the relative paths do not work. This is because the relative path is constructed from the directory where the script is being invoked. A suggested workaround is to pick up the base directory where the software is installed from the environment or by

using the **dirname** cmd or api. The workflow system can set appropriate environment variables while launching jobs on the Grid.

No hard-coded paths

The algorithms should not hard-code any directory paths in the code. All directories paths should be picked up explicitly either from the environment (specifying environment variables) or from command line options passed to the algorithm code.

Wrapping legacy codes with a shell wrapper

When wrapping a legacy code in a script (or another program), it is necessary that the wrapper knows where the executable lives. This is accomplished using an environmental variable. Be sure to include this detail in the component description when submitting a component for use on the Grid -- include a brief descriptive name like GDA_BIN.

Propagating back the right exitcode

A job in the workflow is only released for execution if its parents have executed successfully. Hence, it is very important that the algorithm codes exit with the correct error code in case of success and failure. The algorithms should exit with a status of 0 in case of success, and a non zero status in case of error. Failure to do so will result in erroneous workflow execution where jobs might be released for execution even though their parents had exited with an error.

The algorithm codes should catch all errors and exit with a non zero exitcode. The successful execution of the algorithm code can only be determined by an exitcode of 0. The algorithm code should not rely upon something being written to the stdout to designate success for e.g. if the algorithm code writes out to the stdout SUCCESS and exits with a non zero status the job would be marked as failed.

In *nix, a quick way to see if a code is exiting with the correct code is to execute the code and then execute `echo $?.`

```
$ component-x input-file.lisp
... some output ...
$ echo $?
0
```

If the code is not exiting correctly, it is necessary to wrap the code in a script that tests some final condition (such as the presence or format of a result file) and uses `exit` to return correctly.

Static vs. Dynamically Linked Libraries

Since there is no way to know the profile of the machine that will be executing the code, it is important that dynamically linked libraries are avoided or that reliance on them is kept to a minimum. For example, a component that requires `libc 2.5` may or may not run on a machine that uses `libc 2.3`. On *nix, you can use the **ldd** command to see what libraries a binary depends on.

If for some reason you install an algorithm specific library in a non standard location make sure to set the `LD_LIBRARY_PATH` for the algorithm in the transformation catalog for each site.

Temporary Files

If the algorithm codes create temporary files during execution, they should be cleared by the codes in case of errors and success terminations. The algorithm codes will run on scratch file systems that will also be used by others. The scratch directories get filled up very easily, and jobs will fail in case of directories running out of free space. The temporary files are the files that are not being tracked explicitly through the workflow generation process.

Handling of stdio

When writing a new application, it often appears feasible to use `stdin` for a single file data, and `stdout` for a single file output data. The `stderr` descriptor should be used for logging and debugging purposes only, never to put data on it. In the *nix world, this will work well, but may hiccup in the Windows world.

We are suggesting that you avoid using `stdio` for data files, because there is the implied expectation that `stdio` data gets magically handled. There is no magic! If you produce data on `stdout`, you need to declare to Pegasus that your `stdout` has your data, and what LFN Pegasus can track it by. After the application is done, the data product will be a remote file just like all other data products. If you have an input file on `stdin`, you must track it in a similar manner. If you produce logs on `stderr` that you care about, you must track it in a similar manner. Think about it this way: Whenever you are redirecting `stdio` in a *nix shell, you will also have to specify a file name.

Most execution environments permit to connect `stdin`, `stdout` or `stderr` to any file, and Pegasus supports this case. However, there are certain very specific corner cases where this is not possible. For this reason, we recommend that in new code, you avoid using `stdio` for data, and provide alternative means on the commandline, i.e. via **--input *fn*** and **--output *fn*** commandline arguments instead relying on `stdin` and `stdout`.

Configuration Files

If your code requires a configuration file to run and the configuration changes from one run to another, then this file needs to be tracked explicitly via the Pegasus WMS. The configuration file should not contain any absolute paths to any data or libraries used by the code. If any libraries, scripts etc need to be referenced they should refer to relative paths starting with a `./xyz` where `xyz` is a tracked file (defined in the workflow) or as `$ENV-VAR/xyz` where `$ENV-VAR` is set during execution time and evaluated by your application code internally.

Code Invocation and input data staging by Pegasus

Pegasus will create one temporary directory per workflow on each site where the workflow is planned. Pegasus will stage all the files required for the execution of the workflow in these temporary directories. This directory is shared by all the workflow components that executed on the site. You will have no control over where this directory is placed and as such you should have no expectations about where the code will be run. The directories are created per workflow and not per job/algorithm/task. Suppose there is a component `component-x` that takes one argument: `input-file.lisp` (a file containing the data to be operated on). The staging step will bring `input-file.lisp` to the temporary directory. In *nix the call would look like this:

```
$ /nfs/software/component-x input-file.lisp
```

Note that Pegasus will call the component using the full path to the component. If inside your code/script you invoke some other code you cannot assume a path for this code to be relative or absolute. You have to resolve it either using a `dirname $0` trick in shell assuming the child code is in the same directory as the parent or construct the path by expecting an environment variable to be set by the workflow system. These env variables need to be explicitly published so that they can be stored in the transformation catalog.

Now suppose that internally, `component-x` writes its results to `/tmp/component-x-results.lisp`. This is not good. Components should not expect that a `/tmp` directory exists or that it will have permission to write there. Instead, `component-x` should do one of two things: 1. write `component-x-results.lisp` to the directory where it is run from or 2. `component-x` should take a second argument `output-file.lisp` that specifies the name and path of where the results should be written.

Logical File naming in DAX

The logical file names used by your code can be of two types.

- Without a directory path e.g. `f.a`, `f.b` etc
- With a directory path e.g. `a/1/f.a`, `b/2/f.b`

Both types of files are supported. We will create any directory structure mentioned in your logical files on the remote execution site when we stage in data as well as when we store the output data to a permanent location. An example invocation of a code that consumes and produces files will be

```
$/bin/test --input f.a --output f.b
```

OR

```
$/bin/test --input a/1/f.a --output b/1/f.b
```

Note

A logical file name should never be an absolute file path, e.g. /a/1/f.a In other words, there should not be a starting slash (/) in a logical filename.

Chapter 12. Funding, citing, and anonymous usage statistics

Citing Pegasus in Academic Works

The preferred generic way to cite Pegasus is:

Pegasus: a Framework for Mapping Complex Scientific Workflows onto Distributed Systems, Ewa Deelman, Gurmeet Singh, Mei-Hui Su, James Blythe, Yolanda Gil, Carl Kesselman, Gaurang Mehta, Karan Vahi, G. Bruce Berriman, John Good, Anastasia Laity, Joseph C. Jacob, Daniel S. Katz. *Scientific Programming Journal*, Vol 13(3), 2005, Pages 219-237.

Usage Statistics Collection

Purpose

Pegasus WMS is primarily a NSF funded project as part of the NSF SI2 [http://www.nsf.gov/funding/pgm_summ.jsp?pims_id=504817] track. The SI2 program focuses on robust, reliable, usable and sustainable software infrastructure that is critical to the CIF21 vision. As part of the requirements of being funded under this program, Pegasus WMS is required to gather usage statistics of Pegasus WMS and report it back to NSF in annual reports. The metrics will also enable us to improve our software as they will include errors encountered during the use of our software.

Overview

We plan to instrument and augment the following clients in our distribution to report the metrics.

- pegasus-plan
- pegasus-transfer
- pegasus-monitord

For the Pegasus WMS 4.2 release, only the pegasus-plan client has been instrumented to send metrics.

All the metrics are sent in JSON format to a server at USC/ISI over HTTP. The data reported is as generic as possible and is listed in detail in the section titled "Metrics Collected".

Configuration

By default, the clients will report usage metrics to a server at ISI. However, users have an option to configure the report by setting the following environment variables

- PEGASUS_METRICS

A boolean value (true | false) indicating whether metrics reporting is turned ON/OFF

- PEGASUS_USER_METRICS_SERVER

A comma separated list of URLs of the servers to which to report the metrics in addition to the default server.

Metrics Collected

All metrics are sent in JSON format and the metrics sent by the various clients include the following data

Table 12.1. Common Data Sent By Pegasus WMS Clients

JSON KEY	DESCRIPTION
client	the name of the client (e.g "pegasus-plan")
version	the version of the client
type	type of data - "metrics" "error"
start_time	start time of the client (in epoch seconds with millisecond precision)
end_time	end time of the client (in epoch seconds with millisecond precision)
duration	the duration of the client
exitcode	the exitcode with which the client exited
wf_uuid	the uuid of the executable workflow. It is generated by pegasus-plan at planning time.

Pegasus Planner Metrics

The metrics messages sent by the planner in addition include the following data

Table 12.2. Metrics Data Sent by pegasus-plan

JSON KEY	DESCRIPTION
root_wf_uuid	the root workflow uuid. For non hierarchal workflows the root workflow uuid is the same as the workflow uuid.
data_config	the data configuration mode of pegasus
compute_tasks	the number of compute tasks in the workflow
dax_tasks	the number of dax tasks in the abstract workflow (DAX)
dag_tasks	the number of dag tasks in the abstract workflow (DAX)
total_tasks	the number of the total tasks in the abstract workflow (DAX)
compute_jobs	the number of compute jobs in the executable workflow
clustered_jobs	the number of clustered jobs in the executable workflow.
si_tx_jobs	the number of data stage-in jobs in the executable workflow.
so_tx_jobs	the number of data stage-out jobs in the executable workflow.
inter_tx_jobs	the number of inter site data transfer jobs in the executable workflow.
reg_job	the number of registration jobs in the executable workflow.
cleanup_jobs	the number of cleanup jobs in the executable workflow.
create_dir_jobs	the number of create directory jobs in the executable workflow.
dax_jobs	the number of sub workflows corresponding to dax tasks in the executable workflow.
dag_jobs	the number of sub workflows corresponding to dag tasks in the executable workflow.
chmod_jobs	the number of jobs that set the xbit of the staged executables

JSON KEY	DESCRIPTION
total_jobs	the total number of jobs in the workflow

In addition if pegasus-plan encounters an error during the planning process the metrics message has an additional field in addition to the fields listed above.

Table 12.3. Error Message sent by pegasus-plan

JSON KEY	DESCRIPTION
error	the error payload is the stack trace of errors caught during planning

Note

pegasus-plan leaves a copy of the metrics sent in the workflow submit directory in the file ending with ".metrics" extension. As a user you will always have access to the metrics sent.

Chapter 13. Glossary

Glossary

A

Abstract Workflow See DAX

C

Concrete Workflow See Executable Workflow

Condor-G A task broker that manages jobs to run at various distributed sites, using Globus GRAM to launch jobs on the remote sites.<http://cs.wisc.edu/condor>

Clustering The process of clustering short running jobs together into a larger job. This is done to minimize the scheduling overhead for the jobs. The scheduling overhead is only incurred for the clustered job. For example if scheduling overhead is x seconds and 10 jobs are clustered into a larger job, the scheduling overhead for 10 jobs will be x instead of 10x.

D

DAGMan The workflow execution engine used by Pegasus.

Directed Acyclic Graph (DAG) A graph in which all the arcs (connections) are unidirectional, and which has no loops (cycles).

DAX The workflow input in XML format given to Pegasus in which transformations and files are represented as logical names. It is an execution-independent specification of computations

Deferred Planning Planning mode to set up Pegasus. In this mode, instead of mapping the job at submit time, the decision of mapping a job to a site is deferred till a later point, when the job is about to be run or near to run.

E

Executable Workflow A workflow automatically generated by Pegasus in which files are represented by physical filenames, and in which sites or hosts have been selected for running each task.

F

Full Ahead Planning Planning mode to set up Pegasus. In this mode, all the jobs are mapped before submitting the workflow for execution to the grid.

G

Globus The Globus Alliance is a community of organizations and individuals developing fundamental technologies behind the "Grid," which lets people share computing power, databases, instruments, and other on-line tools securely

across corporate, institutional, and geographic boundaries without sacrificing local autonomy.

See Globus Toolkit

Globus Toolkit

Globus Toolkit is an open source software toolkit used for building Grid systems and applications.

GRAM

A Globus service that enable users to locate, submit, monitor and cancel remote jobs on Grid-based compute resources. It provides a single protocol for communicating with different batch/cluster job schedulers.

Grid

A collection of many compute resources , each under different administrative domains connected via a network (usually the Internet).

GridFTP

A high-performance, secure, reliable data transfer protocol optimized for high-bandwidth wide-area networks. It is based upon the Internet FTP protocol, and uses basic Grid security on both control (command) and data channels.

Grid Service

A service which uses standardized web service mechanisms to model and access stateful resources, perform lifecycle management and query resource state. The Globus Toolkit includes core grid services for execution management, data management and information management.

L

Logical File Name

The unique logical identifier for a data file. Each LFN is associated with a set of PFN's that are the physical instantiations of the file.

M

Metadata

Any attributes of a dataset that are explicitly represented in the workflow system. These may include provenance information (e.g., which component was used to generate the dataset), execution information (e.g., time of creation of the dataset), and properties of the dataset (e.g., density of a node type).

Monitoring and Discovery Service

A Globus service that implements a site catalog.

P

Physical File Name

The physical file name of the LFN.

Partitioner

A tool in Pegasus that slices up the DAX into smaller DAX's for deferred planning.

Pegasus

A system that maps a workflow instance into an executable workflow to run on the grid.

R

Replica Catalog

A catalog that maps logical file names on to physical file names.

Replica Location Service

A Globus service that implements a replica catalog

S

Site

A set of compute resources under a single administrative domain.

T	Site Catalog	A catalog indexed by logical site identifiers that maintains information about the various grid sites. The site catalog can be populated from a static database or maybe populated dynamically by monitoring tools.
	Transformation	Any executable or code that is run as a task in the workflow.
	Transformation Catalog	A catalog that maps transformation names onto the physical pathnames of the transformation at a given grid site or local test machine.
W	Workflow Instance	A workflow created in Wings and given to Pegasus in which workflow components and files are represented as logical names. It is an execution-independent specification of computations

Appendix A. Tutorial VM

Introduction

This appendix provides information on how to launch the Pegasus Tutorial VM. The VM is a quick way to get started using Pegasus. It comes pre-configured with Pegasus, DAGMan and Condor so that you can begin running workflows immediately.

In the following sections we will cover how to start, log into, and stop the tutorial VM locally, using the VirtualBox virtualization software, and remotely on Amazon EC2 and FutureGrid.

VirtualBox

VirtualBox is a free desktop virtual machine manager. You can use it to run the Pegasus Tutorial VM on your desktop or laptop.

Install VirtualBox

First, download and install the VirtualBox platform package from the VirtualBox website: <https://www.virtualbox.org>

Download VM Image

Next, download the Pegasus Tutorial VM from the Pegasus download page: <http://pegasus.isi.edu/downloads>

Unzip the downloaded file and move the .vmdk file it contains to somewhere that you can find it later.

Create Virtual Machine

Start VirtualBox. You should get a screen that looks like this:

Figure A.1. VirtualBox Welcome Screen

Click on the "New" button. The "Create New Virtual Machine Wizard" will appear:

Figure A.2. Create New Virtual Machine Wizard

Click "Continue" to get to the VM Name and OS Type step:

Figure A.3. VM Name and OS Type

In the Name field type "Pegasus Tutorial". Set the Operating System to "Linux" and the Version to "Red Hat (64 bit)".

Warning

Make sure to select "Red Hat (64 bit)" as the Version. If this is incorrect the virtual machine may not be able to start.

Click "Continue" to get to the Memory step. You can leave this at the default of 512 MB.

Figure A.4. Memory

Click "Continue" again to get to the "Virtual Hard Disk" step:

Figure A.5. Virtual Hard Disk

Leave "Start-up Disk" checked. Choose "Use existing hard disk". Click the folder icon and locate the .vmdk file that you downloaded earlier.

When you have selected the .vmdk file, choose "Open" and then click "Continue" to get to the Summary page:

Figure A.6. Summary

Click "Create". You will get back to the welcome screen showing the new virtual machine:

Figure A.7. Welcome Screen with new virtual machine

Click on the name of the virtual machine and then click "Start". After a few seconds you should get to the login screen:

Figure A.8. Login Screen

Log in as user "**tutorial**" with password "**pegasus**".

After you log in you can return to the tutorial chapter to complete the tutorial.

Terminating the VM

When you are done with the tutorial you can shut down the VM by typing:

```
$ sudo /sbin/poweroff
```

at the prompt and then enter the tutorial user's password.

Alternatively, you can just close the window and choose "Power off the machine".

Amazon EC2

In order to launch the tutorial VM you need to sign up for an Amazon Web Services account here: <http://aws.amazon.com>

Launching the VM

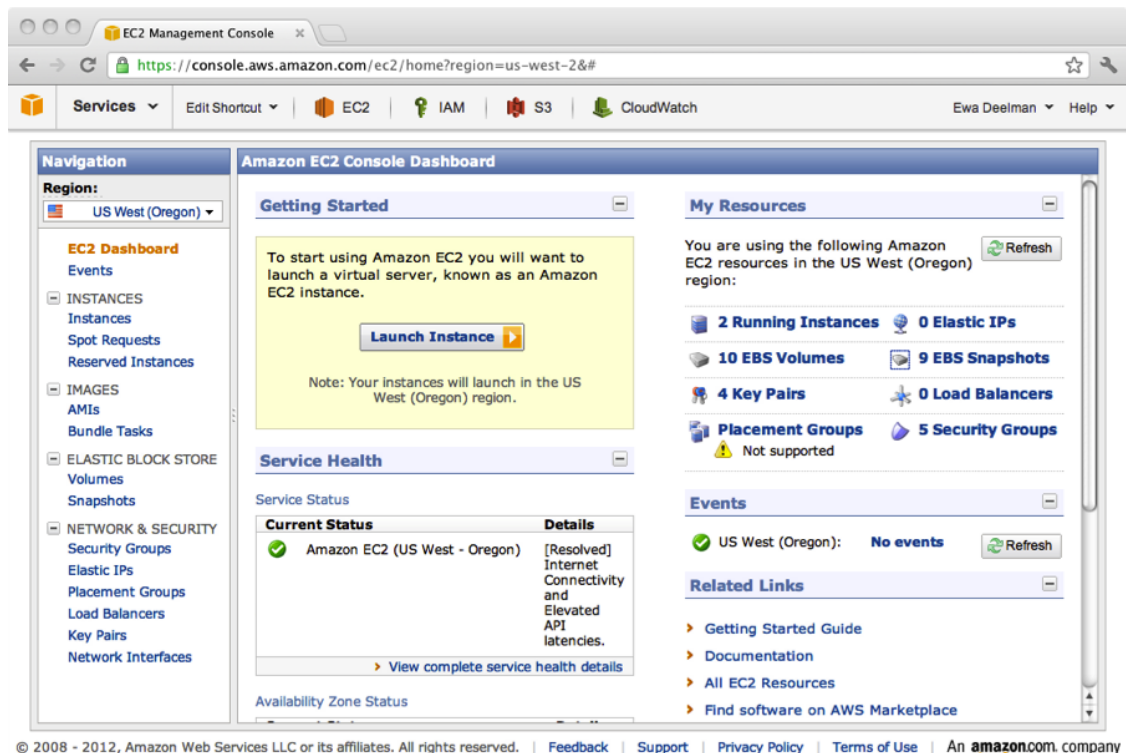

Once you have an account, sign into the AWS Management Console at this URL: <http://console.aws.amazon.com>. You will get a page that looks like this:

Figure A.9. AWS Management Console

Choose the "EC2" icon under "Amazon Web Services". You will get this page:

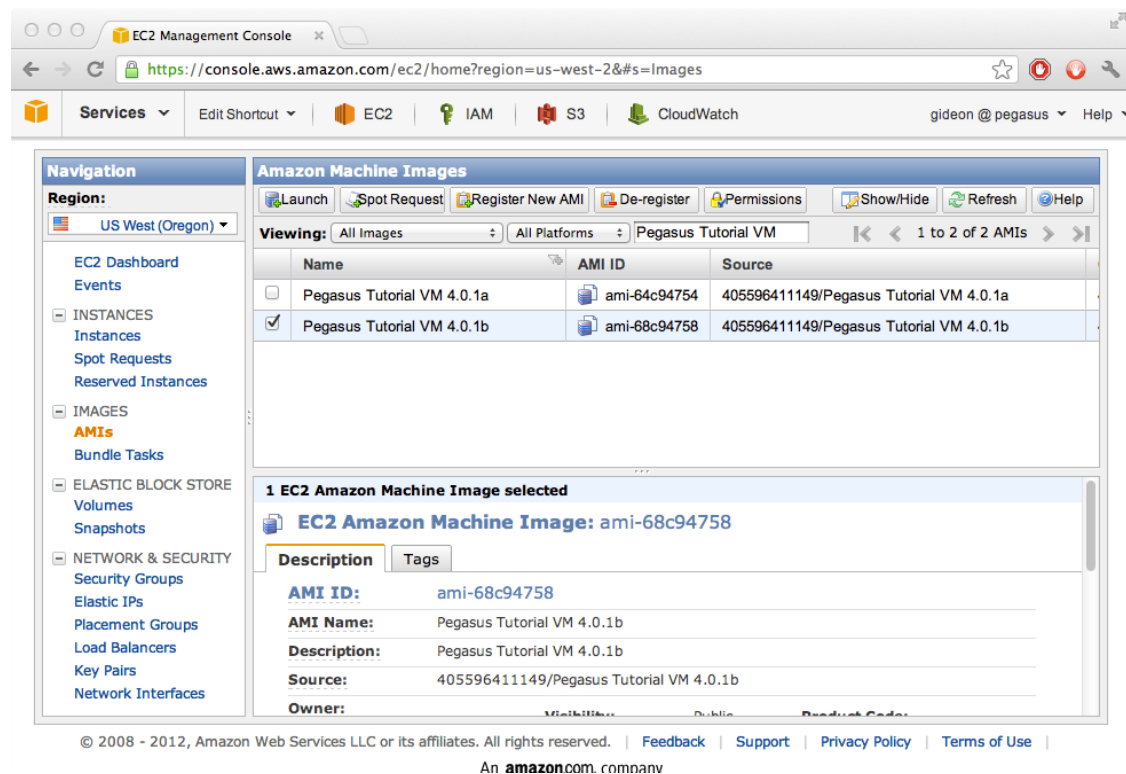

Figure A.10. EC2 Management Console

First, make sure the “Region:” drop-down in the upper left-hand corner is set to “US West (Oregon)”.

Click on the “AMIs” link on the left side and set “Viewing:” to “All Images”, “All Platforms”, and type “Pegasus Tutorial VM” in the search box:

Figure A.11. Locating the Tutorial VM

You will see several versions of the VM. If you don't see any AMIs named "Pegasus Tutorial VM" you may need to click the Refresh button. We update the VM regularly, so your search results will not match the picture above.

Check the check box next to the latest Pegasus Tutorial VM and click the “Launch” button. The "Request Instances Wizard" will pop up:

Figure A.12. Request Instances Wizard: Step 1

Request Instances Wizard Cancel

CHOOSE AN AMI **INSTANCE DETAILS** CREATE KEY PAIR CONFIGURE FIREWALL REVIEW

Provide the details for your instance(s). You may also decide whether you want to launch your instances as "on-demand" or "spot" instances.

Number of Instances: 1 **Instance Type:** Large (m1.large, 7.5 GiB)

Launch Instances

EC2 Instances let you pay for compute capacity by the hour with no long term commitments. This transforms what are commonly large fixed costs into much smaller variable costs.

Launch into: ☒ EC2 ☐ VPC

Availability Zone: No Preference

☐ Request Spot Instances

[< Back](#) [Continue >](#)

In the first step of the Request Instances Wizard choose the “Large” instance type and click “Continue”:

Figure A.13. Request Instances Wizard: Step 2

Request Instances Wizard Cancel

CHOOSE AN AMI **INSTANCE DETAILS** CREATE KEY PAIR CONFIGURE FIREWALL REVIEW

Number of Instances: 1 **Availability Zone:** No Preference

Advanced Instance Options

Here you can choose a specific **kernel** or **RAM disk** to use with your instances. You can also choose to enable CloudWatch Detailed Monitoring or enter data that will be available from your instances once they launch.

Kernel ID: Use Default **RAM Disk ID:** Use Default

Monitoring: ☐ Enable CloudWatch detailed monitoring for this instance (additional charges will apply)

User Data:

☒ as text ☐ as file

☐ base64 encoded

Termination Protection: ☐ Prevention against accidental termination. **Shutdown Behavior:** Stop

IAM Role: ☒ None

[< Back](#) [Continue >](#)

Don’t change anything on the “Advanced Instance Options” step and click “Continue”:

Figure A.14. Request Instances Wizard: Step 3

Request Instances Wizard Cancel

✓ CHOOSE AN AMI **INSTANCE DETAILS** CREATE KEY PAIR CONFIGURE FIREWALL REVIEW

Availability Zone: No Preference

Storage Device Configuration
 Your instance will be launched with the following storage device settings. Edit these settings to add EBS volumes, instance store volumes, or edit the settings of the root volume.

☒ Root Volume
 ☐ EBS Volumes
 ☐ Instance Store Volumes

Optionally edit the the root volume of your instance.

Volume Size: 10 GIB
 Delete on Termination: ☒

Device: /dev/sda1 Save

Type	Device	Snapshot ID	Size	Delete on Termination
Root	/dev/sda1	snap-1f2bd675	10GiB	true

Back Continue

On the “Storage Device Configuration” step make sure “Delete on Termination” is set to "true", then click “Continue”:

Figure A.15. Request Instances Wizard: Step 4

Request Instances Wizard Cancel

✓ CHOOSE AN AMI **INSTANCE DETAILS** CREATE KEY PAIR CONFIGURE FIREWALL REVIEW

Add tags to your instance to simplify the administration of your EC2 infrastructure. A form of metadata, tags consist of a case-sensitive key/value pair, are stored in the cloud and are private to your account. You can create user-friendly names that help you organize, search, and browse your resources. For example, you could define a tag with key = Name and value = Webserver. You can add up to 10 unique keys to each instance along with an optional value for each key. For more information, go to [Using Tags](#) in the *EC2 User Guide*.

Key (127 characters maximum)	Value (255 characters maximum)	Remove
Name	Pegasus Tutorial	✗
		✗

Add another Tag. (Maximum of 10)

Back Continue

On the next step type “Pegasus Tutorial” into the “Value” field and click “Continue”:

Figure A.16. Request Instances Wizard: Step 5

Request Instances Wizard Cancel

✓ CHOOSE AN AMI ✓ INSTANCE DETAILS **CREATE KEY PAIR** CONFIGURE FIREWALL REVIEW

Public/private key pairs allow you to securely connect to your instance after it launches. To create a key pair, enter a name and click **Create & Download your Key Pair**. You will then be prompted to save the private key to your computer. Note, you only need to generate a key pair once - not each time you want to deploy an Amazon EC2 instance.

☒ **Choose from your existing Key Pairs**

Your existing Key Pairs*: gideon-keypair-oregon

☐ Create a new Key Pair

☐ Proceed without a Key Pair

Back Continue

On the next page choose one of your existing key pairs and click “Continue”. If you don’t have an existing key pair you can also choose “Proceed without a Key Pair” (you will log in with a username/password).

Security groups determine whether a network port is open or blocked on your instances. You may use an existing security group, or we can help you create a new security group to allow access to your instances using the suggested ports below. Add additional ports now or update your security group anytime using the Security Groups page.

☐ Choose one or more of your existing Security Groups

☒ **Create a new Security Group**

Group Name Pegasus Tutorial

Group Description SSH

Inbound Rules

Create a new rule: Custom TCP rule

Port range: 22
(e.g., 80 or 49152-65535)

Source: 0.0.0.0/0
(e.g., 192.168.2.0/24, sg-47ad482e, or 1234567890/default)

+ Add Rule

TCP Port (Service)	Source	Action
22 (SSH)	0.0.0.0/0	Delete

Back Continue

On the next page choose “Create a new Security Group”. Name the security group “Pegasus Tutorial” and give it a description. Create an inbound TCP rule to allow connections on port 22 (SSH) from source 0.0.0.0/0 and click "Add Rule". Then click “Continue”.

Note that you will only need to create this security group once. If you launch the Pegasus Tutorial VM again the security group should appear in the list of existing security groups.

Figure A.18. Request Instances Wizard: Step 7

Request Instances Wizard Cancel

CHOOSE AN AMI INSTANCE DETAILS CREATE KEY PAIR CONFIGURE FIREWALL **REVIEW**

Please review the information below, then click **Launch**.

Tenancy: Default

Kernel ID: Use Default **Shutdown Behavior:** Stop

RAM Disk ID: Use Default

Network Interfaces:

Secondary IP Addresses:

User Data:

IAM Role: [Edit Advanced Details](#)

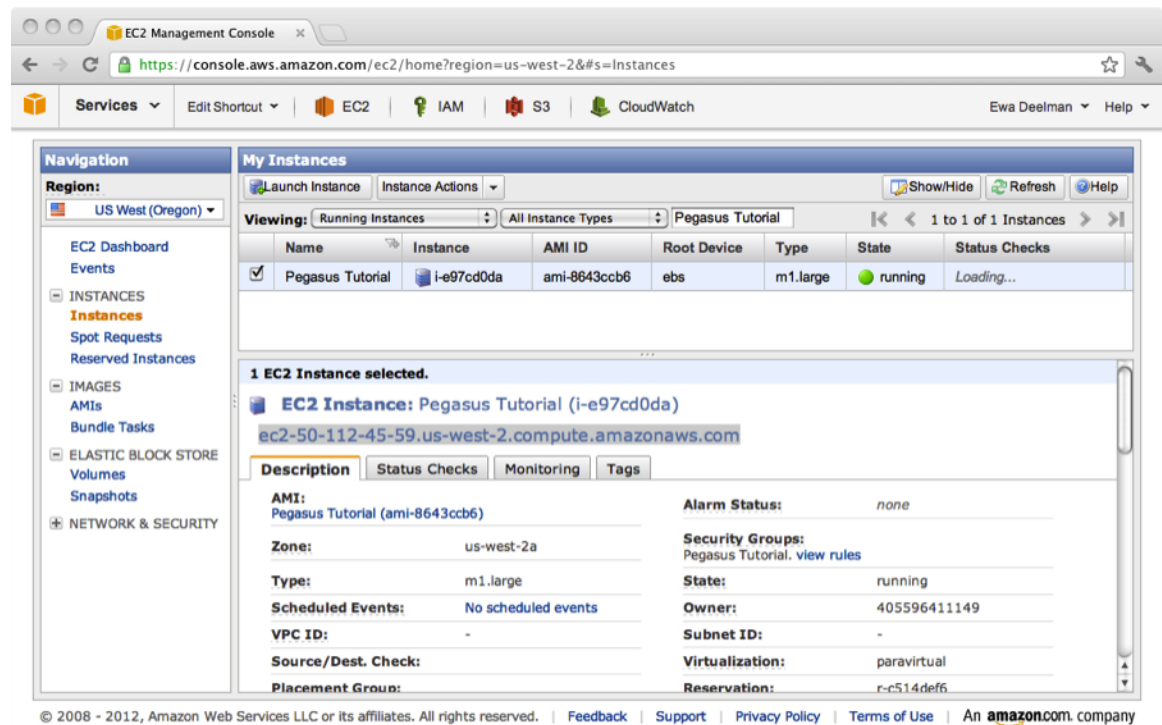

Key Pair Name: gideon-keypair-oregon [Edit Key Pair](#)

Security Group(s): sg-ec29bfcd [Edit Firewall](#)

[< Back](#) [Launch](#)

On the last step of the wizard validate your selections and click “Launch”.

Figure A.19. Running Instances

Finally, navigate to the “Instances” section and check the checkbox next to the “Pegasus Tutorial” instance. Copy the DNS name to the clipboard. In this example the name is: **ec2-50-112-45-59.us-west-2.compute.amazonaws.com**. Yours will almost surely be different.

At this point your VM will take a few minutes to boot. Wait until the “Status Checks” column reads: “2/2 checks passed” before continuing. You may need to click the Refresh button.

Logging into the VM

Log into the VM using SSH. The username is ‘**tutorial**’ and the password is ‘**pegasus**’.

On UNIX machines such as Linux or Mac OS X you can log in via SSH by opening a terminal and typing:

```
$ ssh tutorial@ec2-50-112-45-59.us-west-2.compute.amazonaws.com
The authenticity of host 'ec2-50-112-45-59.us-west-2.compute.amazonaws.com (50.112.45.59)' can't be
established.
RSA key fingerprint is 56:b0:11:ba:8f:98:ba:dd:75:f6:3c:09:ef:b9:2a:ac.
Are you sure you want to continue connecting (yes/no)? yes
tutorial's password: pegasus
[tutorial@localhost ~]$
```

where “ec2-50-112-45-59.us-west-2.compute.amazonaws.com” is the DNS name of your VM that you copied from the AWS Management Console.

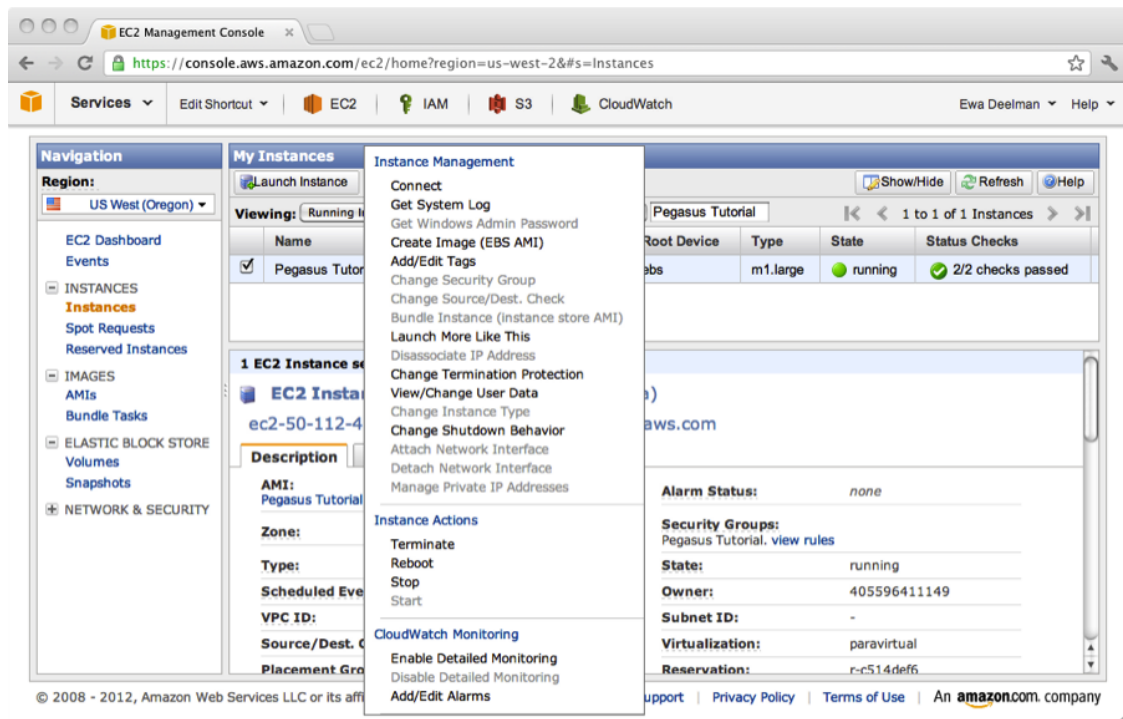

If you are on Windows you will need to install an SSH client. You can download the PuTTY SSH client and find documentation for how to configure it here: <http://www.chiark.greenend.org.uk/~sgtatham/putty>

Shutting down the VM

When you are finished with the tutorial, make sure you terminate the VM. If you forget to do this you will be charged for all of the hours that the VM runs.

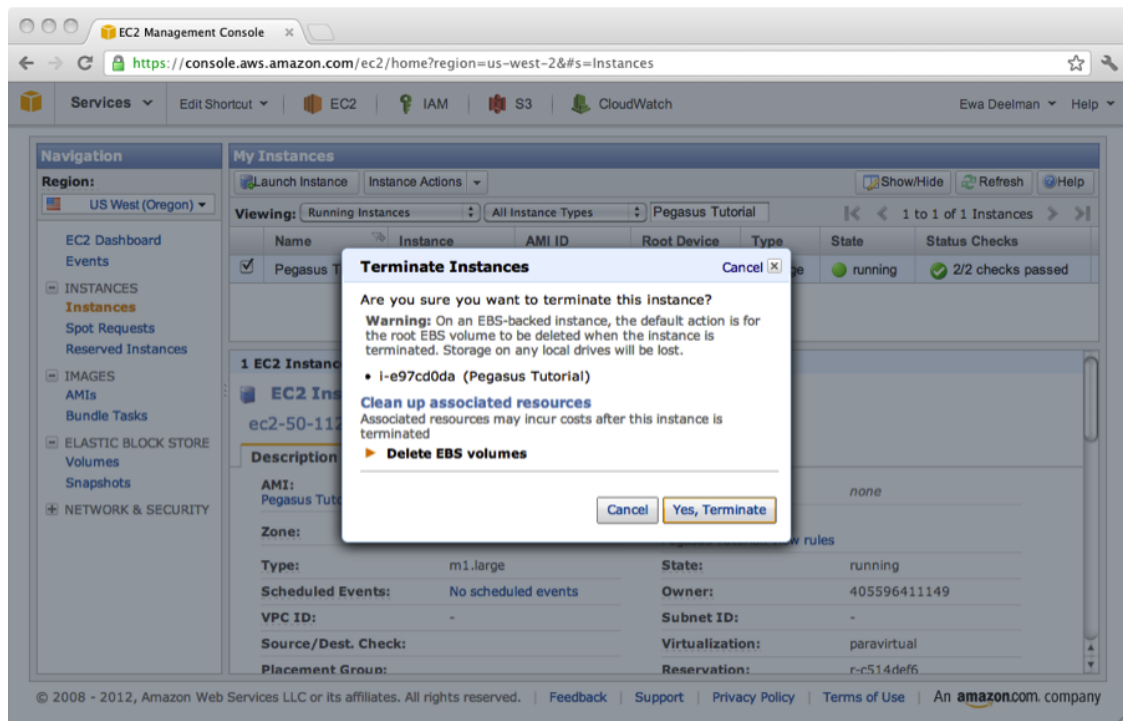

To terminate the VM click on “Instances” link on the left side of the AWS Management Console, check the box next to the “Pegasus Tutorial” VM, and click “Instance Actions”-->“Terminate”:

Figure A.20. Terminate Instance

Then click "Yes, terminate":

Figure A.21. Yes, Terminate Instance

FutureGrid

The FutureGrid Project (<https://portal.futuregrid.org>) is a cloud computing testbed supported by the National Science Foundation. It consists of a collection of computational, networking, and storage resources located throughout the United States. The goal of the FutureGrid Project is to study the behavior and usefulness of cloud computing technologies. It provides a platform where researchers can experiment with different cloud technologies.

Getting Started

The Pegasus Tutorial VM has been deployed to the FutureGrid "India" site using OpenStack. In order to launch the VM, you will need to have a FutureGrid account. You can get one by going to <https://portal.futuregrid.org> and either joining an existing project, or starting a new project.

If you are not familiar with using OpenStack on FutureGrid, we recommend that you review the "Using OpenStack on FutureGrid" tutorial found here: <https://portal.futuregrid.org/tutorials/openstack>.

Launching the VM

First, log into the India site using your FutureGrid username and password:

```
$ ssh USERNAME@india.futuregrid.org
```

If you have not already done so, source the `novarc` file that contains your OpenStack credentials:

```
$ source ~/.futuregrid/openstack/novarc
```

Also, load the `euca2ools` module to add them to your environment:

```
$ module load euca2ools
```

Next, query OpenStack to find the latest Pegasus Tutorial VM image:

```
$ euca-describe-images | grep PegasusTutorialVM
IMAGE ami-0000003e juve/PegasusTutorialVM-4.0.1.fg.manifest.xml available public x86_64 ...
```

Find the image ID (`ami-0000003e` in the example above). If you get multiple results, use the latest version.

Launch the tutorial VM using the `euca-run-instances` command with the image ID you found in the previous step:

```
$ euca-run-instances ami-0000003e
RESERVATION    r-y9ue0rs7    461884eef90047fbb4eb9ec92f22a1e3    default
INSTANCE      i-00000c38    ami-0000003e    server-3128    server-3128    pending    ...
```

Note the instance ID (`i-00000c38` in the example). Monitor the status of your VM by invoking the `euca-describe-instances` command periodically with the instance ID until the VM status changes from "pending" to "running":

```
$ euca-describe-instances i-00000c38
RESERVATION    r-y9ue0rs7    461884eef90047fbb4eb9ec92f22a1e3    default
INSTANCE      i-00000c38    ami-0000003e    server-3128    server-3128    pending    ...
$ ...
$ euca-describe-instances i-00000c38
RESERVATION    r-y9ue0rs7    461884eef90047fbb4eb9ec92f22a1e3    default
INSTANCE      i-00000c38    ami-0000003e    149.165.158.123    server-3128    running    ...
```

Note down the IP address of the instance (`149.165.158.123` in the example). Log into the VM as the tutorial user:

```
$ ssh tutorial@149.165.158.123
```

The password is "pegasus".

At this point you should return to the tutorial chapter and complete the tutorial.

Terminating the VM

Log out of the VM by typing:

```
$ exit
```

Using the instance ID you found in the last section (NOT the image ID), terminate the VM by typing:

```
$ euca-terminate-instances i-00000c38
INSTANCE      i-00000c38
```

When you invoke `euca-describe-instances` you should no longer see the VM running (you should not get any output):

```
$ euca-describe-instances i-00000c38
$
```
